An Oracle White Paper
September 2014

Oracle: Big Data for the Enterprise
Executive Summary

Today the term big data draws a lot of attention, but behind the hype there’s a simple story. For decades, companies have been making business decisions based on transactional data stored in relational databases. Beyond that critical data, however, is a potential treasure trove of non-traditional, less structured data: weblogs, social media, email, sensors, and photographs that can be mined for useful information. Decreases in the cost of both storage and compute power have made it feasible to collect this data - which would have been thrown away only a few years ago. As a result, more and more companies are looking to include non-traditional yet potentially very valuable data with their traditional enterprise data in their business intelligence analysis.

To derive real business value from big data, you need the right tools to not only capture a wide variety of data types from new sources, and to be able to easily analyze it within the context of all your enterprise data. Oracle offers unique products like Oracle Big Data SQL that enable the full power of Oracle SQL on all of that data across Oracle Database, Hadoop and NoSQL data stores.
Introduction

With Oracle Big Data Appliance, Oracle Big Data SQL and Oracle Big Data Connectors, Oracle is the first vendor to offer a complete and integrated solution to address the full spectrum of enterprise big data requirements. Oracle’s big data strategy is centered on the idea that you can evolve your current enterprise data architecture to incorporate big data and deliver business value across all data leveraging the full power of Oracle SQL. By evolving your current enterprise architecture, you can leverage the proven reliability, security and performance of your Oracle systems extended with new Big Data systems from Oracle.

Defining Big Data

Big data typically refers to the following types of data:

- Traditional enterprise data – includes customer information from CRM systems, transactional ERP data, web store transactions, and general ledger data.
- Machine-generated /sensor data – includes Call Detail Records (“CDR”), weblogs, smart meters, manufacturing sensors, equipment logs (often referred to as digital exhaust), trading systems data.
- Social data – includes customer feedback streams, micro-blogging sites like Twitter, social media platforms like Facebook.

The McKinsey Global Institute estimates that data volume is growing 40% per year, and will grow 44x between 2009 and 2020. But while it’s often the most visible parameter, volume of data is not the only characteristic that matters. In fact, there are four key characteristics that define big data:

- Volume. Machine-generated data is produced in much larger quantities than non-traditional data. For instance, a single jet engine can generate 10TB of data in 30 minutes. With more than 25,000 airline flights per day, the daily volume of just this single data source runs into the Petabytes. Smart meters and heavy industrial equipment like oil refineries and drilling rigs generate similar data volumes, compounding the problem.
- Velocity. Social media data streams – while not as massive as machine-generated data – produce a large influx of opinions and relationships valuable to customer relationship management. Even at 140 characters per tweet, the high velocity (or frequency) of Twitter data ensures large volumes (over 8 TB per day).
- Variety. Traditional data formats tend to be relatively well defined by a data schema and change slowly. In contrast, non-traditional data formats exhibit a dizzying rate of
change. As new services are added, new sensors deployed, or new marketing campaigns executed, new data types are needed to capture the resultant information.

- Value. The economic value of different data varies significantly. Typically there is good information hidden amongst a larger body of non-traditional data; the challenge is identifying what is valuable and then transforming and extracting that data for analysis.

To make the most of big data, enterprises must evolve their IT infrastructures to handle these new high-volume, high-velocity, high-variety sources of data and integrate them with the pre-existing enterprise data to be analyzed.

The Importance of Big Data
When big data is distilled and analyzed in combination with traditional enterprise data, enterprises can develop a more thorough and insightful understanding of their business, which can lead to enhanced productivity, a stronger competitive position and greater innovation – all of which can have a significant impact on the bottom line.

For example, in the delivery of healthcare services, management of chronic or long-term conditions is expensive. Use of in-home monitoring devices to measure vital signs, and monitor progress is just one way that sensor data can be used to improve patient health and reduce both office visits and hospital admittance.

Manufacturing companies deploy sensors in their products to return a stream of telemetry. In the automotive industry, systems such as General Motors' OnStar® or Renault’s R-Link®, deliver communications, security and navigation services. Perhaps more importantly, this telemetry also reveals usage patterns, failure rates and other opportunities for product improvement that can reduce development and assembly costs.

The proliferation of smart phones and other GPS devices offers advertisers an opportunity to target consumers when they are in close proximity to a store, a coffee shop or a restaurant. This opens up new revenue for service providers and offers many businesses a chance to target new customers.

Retailers usually know who buys their products. Use of social media and web log files from their ecommerce sites can help them understand who didn’t buy and why they chose not to, information not available to them today. This can enable much more effective micro customer segmentation and targeted marketing campaigns, as well as improve supply chain efficiencies through more accurate demand planning.

Finally, social media sites like Facebook and LinkedIn simply wouldn’t exist without big data. Their business model requires a personalized experience on the web, which can only be delivered by capturing and using all the available data about a user or member.
Building a Big Data Platform

As with data warehousing, web stores or any IT platform, an infrastructure for big data has unique requirements. In considering all the components of a big data platform, it is important to remember that the end goal is to easily integrate your big data with your enterprise data to allow you to conduct deep analytics on the combined data set.

Infrastructure Requirements

The requirements in a big data infrastructure span data acquisition, data organization and data analysis.

Acquire Big Data

The acquisition phase is one of the major changes in infrastructure from the days before big data. Because big data refers to data streams of higher velocity and higher variety, the infrastructure required to support the acquisition of big data must deliver low, predictable latency in both capturing data and in executing short, simple queries; be able to handle very high transaction volumes, often in a distributed environment; and support flexible, dynamic data structures.

NoSQL databases are frequently used to acquire and store big data. They are well suited for dynamic data structures and are highly scalable. The data stored in a NoSQL database is typically of a high variety because the systems are intended to simply capture all data without categorizing and parsing the data into a fixed schema.

For example, NoSQL databases are often used to collect and store social media data. While customer facing applications frequently change, underlying storage structures are kept simple. Instead of designing a schema with relationships between entities, these simple structures often just contain a major key to identify the data point, and then a content container holding the relevant data (such as a customer id and a customer profile). This simple and dynamic structure allows changes to take place without costly reorganizations at the storage layer (such as adding new fields to the customer profile).

Organize Big Data

In classical data warehousing terms, organizing data is called data integration. Because there is such a high volume of big data, there is a tendency to organize data at its initial destination location, thus saving both time and money by not moving around large volumes of data. The infrastructure required for organizing big data must be able to process and manipulate data in the original storage location; support very high throughput (often in batch) to deal with large data processing steps; and handle a large variety of data formats, from unstructured to structured.

Hadoop is a new technology that allows large data volumes to be organized and processed while keeping the data on the original data storage cluster. Hadoop Distributed File System (HDFS) is the long-term storage system for web logs for example. These web logs are turned into browsing behavior (sessions) by running MapReduce programs on the cluster and generating aggregated
results on the same cluster. These aggregated results are then loaded into a Relational DBMS system.

**Analyze Big Data**

Since data is not always moved during the organization phase, the analysis may also be done in a distributed environment, where some data will stay where it was originally stored and be transparently accessed from a data warehouse. The infrastructure required for analyzing big data must be able to support deeper analytics such as statistical analysis and data mining, on a wider variety of data types stored in diverse systems; scale to extreme data volumes; deliver faster response times driven by changes in behavior; and automate decisions based on analytical models. Most importantly, the infrastructure must be able to integrate analysis on the combination of big data and traditional enterprise data. New insight comes not just from analyzing new data, but from analyzing it within the context of the old to provide new perspectives on old problems.

For example, analyzing inventory data from a smart vending machine in combination with the events calendar for the venue in which the vending machine is located, will dictate the optimal product mix and replenishment schedule for the vending machine.

**Rapid Technology Shifts**

Many new technologies have emerged to address the IT infrastructure requirements outlined above. At last count, there were over 120 open source key-value databases for acquiring and storing big data, while Hadoop has emerged as the primary system for organizing big data and relational databases maintain their footprint as a data warehouse and expand their reach into less structured data sets to analyze big data.

These new systems initially led to a divided technology landscape trending towards proprietary APIs for data access. SQL as a language – as shown by the moniker NoSQL – was seemingly abandoned.

Recently that trend is completely reversed, and the #1 hot ticket item in Big Data, and yes also in the NoSQL space, is the enabling of SQL over these key-value or NoSQL stores (including Hadoop).
Oracle’s Big Data Management System

Oracle is the first vendor to offer a complete and integrated data management solution to address the full spectrum of enterprise big data requirements. Oracle’s Big Data Management System is centered on the idea that you can extend your current enterprise information architecture – on engineered systems – to incorporate big data and address all data across these systems with Oracle SQL. Technologies, such as Hadoop and Oracle NoSQL database, run alongside your Oracle data warehouse to deliver integrated and expanded business value and address your big data requirements while adhering to the security policies in your Oracle systems.

Oracle Big Data Appliance

Oracle Big Data Appliance is an engineered system that combines optimized hardware with a comprehensive big data software stack to deliver a complete, easy-to-deploy solution for acquiring and organizing big data.

Oracle Big Data Appliance comes in scalable rack configurations enabling the system to solve development as well as production workloads and to grow as data needs grow across the enterprise.

Oracle Big Data Appliance includes a combination of open source software and specialized software developed by Oracle to address enterprise big data requirements.
The Oracle Big Data Appliance software includes:

- Cloudera Enterprise (Data Hub Edition) with Cloudera Manager
- Oracle Big Data SQL\(^1\)
- Oracle Big Data Appliance Plug-In for Enterprise Manager
- Oracle distribution of the statistical package R
- Oracle NoSQL Database Community Edition\(^2\)
- And Oracle Enterprise Linux operating system and Oracle Java VM

**Oracle Big Data SQL**

Big Data SQL is Oracle’s breakthrough approach to simplifying access and integration to big data sources. Oracle Big Data SQL provides the ability to query all data – in Hadoop, NoSQL datastores, or Oracle Database – in a single SQL statement. Oracle Big Data SQL presents Hadoop and other sources as enhanced external tables, available as of Oracle Database 12.1.0.2. These tables are engineered to transparently map the external semantics of data access – horizontal parallelism, location, and schema – to Oracle internals.

This mapping ensures the best possible optimizations for access and native processing throughout. Oracle Big Data SQL enables users to:

- Express their queries on all data using the world’s richest SQL dialect
- Integrate big data quickly into reports or applications using existing interfaces
- Extend existing Oracle security and access control policies to data stored in Hadoop

While big data may be massive, very often the amount of data that is relevant to a given query is smaller than the total data volume by an order of magnitude or more. This provides an opportunity for tremendous optimization in query performance. Smart Scan for Hadoop – based on Exadata Storage Servers Software – maximizes the performance of Oracle Big Data SQL by providing:

- Data-local scanning: data is read and processed at the point of storage
- Predicate evaluation and projection: only relevant data is transmitted from Hadoop
- Complex parsing: data such as JSON and XML are processed locally at the source
- Bloom Filters: Optimized joins through conversion to Bloom Filter on Hadoop

---

\(^1\) Oracle Big Data SQL is only available on Oracle Big Data Appliance and is a separately licensed component

\(^2\) Oracle NoSQL Database Enterprise Edition is available for Oracle Big Data Appliance as a separately licensed component
Oracle NoSQL Database

Oracle NoSQL Database is a distributed, highly scalable, key-value database based on Oracle Berkeley DB. It delivers a general purpose, enterprise class key value store adding an intelligent driver on top of distributed Berkeley DB. This intelligent driver keeps track of the underlying storage topology, shards the data and knows where data can be placed with the lowest latency. Unlike competitive solutions, Oracle NoSQL Database is easy to install, configure and manage, supports a broad set of workloads, and delivers enterprise-class reliability backed by enterprise-class Oracle support.

![Oracle NoSQL Database Architecture](image)

Figure 2 NoSQL Database Architecture

The primary use cases for Oracle NoSQL Database are low latency data capture and fast querying of that data, typically by key lookup. Oracle NoSQL Database comes with an easy to use Java API and a management framework. The product is available in both an open source community edition and in a priced enterprise edition for large distributed data centers. The former version is installed as part of the Big Data Appliance integrated software.

Oracle Big Data Connectors

Where Oracle Big Data Appliance makes it easy for organizations to acquire and organize new types of data, Oracle Big Data Connectors tightly integrates the big data environment with Oracle Exadata and Oracle Database, so that you can analyze all of your data together with extreme performance. The Oracle Big Data Connectors consist of four components:

Oracle Loader for Hadoop

Oracle Loader for Hadoop (OLH) enables users to use Hadoop MapReduce processing to create optimized data sets for efficient loading and analysis in Oracle Database 11g. Unlike other Hadoop loaders, it generates Oracle internal formats to load data faster and use less database system resources. OLH is added as the last step in the MapReduce transformations as a separate
map – partition – reduce step. This last step uses the CPUs in the Hadoop cluster to format the
data into Oracle’s internal database formats, allowing for a lower CPU utilization and higher data
ingest rates on the Oracle Database platform. Once loaded, the data is permanently available in
the database providing very fast access to this data for general database users leveraging SQL or
business intelligence tools.

Oracle SQL Connector for Hadoop Distributed File System

Oracle SQL Connector for Hadoop Distributed File System (HDFS) is a high speed connector
for accessing data on HDFS directly from Oracle Database. Oracle SQL Connector for HDFS
gives users the flexibility of querying data from HDFS at any time, as needed by their application.

It allows the creation of an external table in Oracle Database, enabling direct SQL access on data
stored in HDFS. The data stored in HDFS can then be queried via SQL, joined with data stored
in Oracle Database, or loaded into the Oracle Database. Access to the data on HDFS is
optimized for fast data movement and parallelized, with automatic load balancing. Data on
HDFS can be in delimited files or in Oracle data pump files created by Oracle Loader for
Hadoop.

Oracle Data Integrator Application Adapter for Hadoop

Oracle Data Integrator Application Adapter for Hadoop simplifies data integration from Hadoop
and an Oracle Database through Oracle Data Integrator’s easy to use interface. Once the data is
accessible in the database, end users can use SQL and Oracle BI Enterprise Edition to access
data.

Enterprises that are already using a Hadoop solution, and don’t need an integrated offering like
Oracle Big Data Appliance, can integrate data from HDFS using Big Data Connectors as a stand-
alone software solution.

Oracle R Connector for Hadoop

Oracle R Connector for Hadoop is an R package that provides transparent access to Hadoop and
to data stored in HDFS.

R Connector for Hadoop provides users of the open-source statistical environment R with the
ability to analyze data stored in HDFS, and to scalably run R models against large volumes of
data leveraging MapReduce processing – without requiring R users to learn yet another API or
language. End users can leverage over 3500 open source R packages to analyze data stored in
HDFS, while administrators do not need to learn R to schedule R MapReduce models in
production environments.

R Connector for Hadoop can optionally be used together with the Oracle Advanced Analytics
Option for Oracle Database. The Oracle Advanced Analytics Option enables R users to
transparently work with database resident data without having to learn SQL or database concepts
but with R computations executing directly in-database.
In-Database Analytics on All Data

Data in Oracle Big Data Appliance in combination with Oracle Exadata is fully SQL enabled by Oracle Big Data SQL. This unique capability enables end users to use the full SQL analytics capabilities across data in both data stores deriving unique business value.

Additionally one of the following easy-to-use tools for in-database, advanced analytics are available when analyzing data:

- **Oracle R Enterprise** – Oracle’s version of the widely used Project R statistical environment enables statisticians to use R on very large data sets without any modifications to the end user experience. Examples of R usage include predicting airline delays at a particular airports and the submission of clinical trial analysis and results.

- **In-Database Data Mining** – the ability to create complex models and deploy these on very large data volumes to drive predictive analytics. End-users can leverage the results of these predictive models in their BI tools without the need to know how to build the models. For example, regression models can be used to predict customer age based on purchasing behavior and demographic data.

- **In-Database Text Mining** – the ability to mine text from micro blogs, CRM system comment fields and review sites combining Oracle Text and Oracle Data Mining. An example of text mining is sentiment analysis based on comments. Sentiment analysis tries to show how customers feel about certain companies, products or activities.

- **In-Database Graph Analysis** – the ability to create graphs and connections between various data points and data sets. Graph analysis creates, for example, networks of relationships determining the value of a customer’s circle of friends. When looking at customer churn customer value is based on the value of his network, rather than on just the value of the customer.

- **In-Database Spatial** – the ability to add a spatial dimension to data and show data plotted on a map. This ability enables end users to understand geospatial relationships and trends much more efficiently. For example, spatial data can visualize a network of people and their geographical proximity. Customers who are in close proximity can readily influence each other’s purchasing behavior, an opportunity which can be easily missed if spatial visualization is left out.

Every one of the analytical components in Oracle Database is valuable. Combining these components creates even more value to the business. Leveraging SQL or a BI Tool to expose the results of these analytics to end users gives an organization an edge over others who do not leverage the full potential of analytics in Oracle Database.

Connections between Oracle Big Data Appliance and Oracle Exadata are via InfiniBand, enabling high-speed data transfer for batch or query workloads. Big Data SQL greatly enhances the performance of these queries by delivering Smart Scan on Hadoop data.
Conclusion

Analyzing new and diverse digital data streams can reveal new sources of economic value, provide fresh insights into customer behavior and identify market trends early on. But this influx of new data creates challenges for IT departments. To derive real business value from big data, you need the right tools to capture and organize a wide variety of data types from different sources, and to be able to easily analyze it within the context of all your enterprise data. By using the Oracle Big Data Appliance and Oracle Big Data Connectors in conjunction with Oracle Exadata, enterprises can acquire, organize and analyze all their enterprise data – including structured and unstructured – to make the most informed decisions.
