Introduction

The amount of data that enterprises are storing and managing is growing rapidly - various industry estimates indicate that data volume is doubling every 2-3 years.

This exponential growth of data presents daunting challenges for IT. First and foremost are storage costs: even though the cost of storage has been declining dramatically, the enormous growth in the volume of data makes storage one of the biggest cost elements of most IT budgets. In addition, as databases grow at accelerating rates, it is difficult to continue to meet performance requirements while staying within budget.

In Oracle Database 12c, several new features have been added to the Oracle Advanced Compression option which enhances the storage management capabilities of Oracle Database. Heat Map automatically tracks modification and query timestamps, providing detailed insights into how data is being accessed. Automatic Data Optimization (ADO) automatically moves and compresses data based on the information collected by Heat Map. Together, these capabilities help to implement Information Lifecycle Management (ILM) strategies.

Heat Map and ADO make it easy to use existing innovations in Oracle Database compression technologies, which can help reduce the cost of managing large amounts of data, while also improving application and database performance. The Oracle Advanced Compression option includes a comprehensive set of compression features designed to reduce costs and improve performance by enabling compression for structured data, unstructured data, database backups, network traffic and for Data Guard Redo.

In addition to Heat Map and ADO, other new features in the Oracle Advanced Compression option include Advanced Network Compression, Advanced Index Compression, Optimization of Flashback Data Archive History Tables, Storage Snapshot Optimization and Online Move Partition to compressed formats.

Each of these Oracle Advanced Compression option features is described in this document.
Oracle Advanced Compression

The Oracle Advanced Compression option provides a comprehensive set of compression capabilities to help customers improve performance while reducing storage costs. It allows IT administrators to significantly reduce their overall database storage footprint by enabling compression for all types of data – relational (table), unstructured (file), index, network and backup data.

Although storage cost savings and optimization across servers (production, development, QA, Test, Backup and etc...) are often seen as the most tangible benefits, all of the features in the Oracle Advanced Compression option are designed to improve performance for all components of your IT infrastructure, including memory, network bandwidth and storage.

Heat Map

Business requirements are not the same for all data in a database. Data goes through various stages in its lifecycle: It starts out as active data, when the data is first inserted and then frequently queried and modified; this data is an ideal candidate for Advanced Row Compression. After some period of time, data typically becomes less active – a time period when it is queried often, for example for report generation, however it is modified rarely; this data is an ideal candidate for Hybrid Columnar Warehouse Compression. In the final stage, data becomes more or less dormant – it is no longer updated and is queried very infrequently, if at all, but it must be kept for compliance and regulatory purposes; this data can be compressed using Hybrid Columnar Archive Compression.

Heat Map is a new Oracle Database feature that collects usage information at the block and segment levels. By using Heat Map in conjunction with Automatic Data Optimization - see the Automatic Data Optimization section below - Oracle Database 12c can automate compression and storage policies based on the usage of the data, reducing storage costs, improving performance and optimizing storage.

At the segment level, Heat Map tracks the timestamps of the most recent modification and query of each table and partition in the database. At the block level, Heat Map tracks the most recent modification timestamp. These timestamps are used by Automatic Data Optimization to define compression and storage policies which will be automatically maintained throughout the lifecycle of the data. Heat Map skips internal operations done for system tasks -- automatically excluding Stats Gathering, DDLs, Table Redefinitions and similar operations. In addition, Heat Map can be disabled at the session level, allowing DBA’s to exclude manual maintenance, avoiding pollution of Heat Map data.

With the data collected by Heat Map, Oracle Database can automatically compress each partition of a table independently based on Heat Map data, implementing compression tiering. This compression tiering can use all forms of Oracle table compression, including: Advanced Row Compression and all levels of Hybrid Columnar Compression (HCC) if the underlying storage supports HCC. Oracle Database can also compress individual database blocks with Advanced Row Compression based on Heat Map data.

Automatic Data Optimization

Automatic Data Optimization (ADO) allows organizations to create policies that implement data compression (Smart Compression) and storage tiering automatically. Smart Compression refers to the ability to utilize Heat Map information to associate compression policies, and compression levels, with actual data usage.

ADO policies define conditions and corresponding actions to be applied to specific objects. Utilizing the information maintained by Heat Map, Oracle Database 12c executes the registered ADO actions for the requested objects to move them to the desired state transparently and automatically.

- ADO policies can be specified at the segment level for tables and partitions, or at the row level for tables.
- Segment level ADO policies are evaluated and executed automatically in the background during maintenance windows, or they can be executed on demand.
Storage tiering can only be specified at the segment level, and can only be triggered by space pressure in the tablespace where the segment currently resides. The DBA can set or change the space pressure threshold using administrative procedures.

Row level ADO policies are evaluated and executed automatically in the background during maintenance windows, or they can be executed on demand.

An ADO policy includes specification of the following:

- Which condition will initiate compression—such as no access or no modification.
- When the policy will take effect—for example, after 30 days (or months or years) of no modification, or 7 days after row or partition creation, or when the tablespace containing the object meets the pre-defined tablespace fullness threshold.

Example ADO Policies:

In this first example, a segment-level ADO policy is created to automatically compress the entire table after there have been no modifications for at least 30 days, using Advanced Row Compression:

```
ALTER TABLE employee ILM ADD POLICY ROW STORE COMPRESS ADVANCED SEGMENT AFTER 30 DAYS OF NO MODIFICATION;
```

In this next example, a row-level ADO policy is created to automatically compress blocks in the table, after no rows in the block have been modified for at least 3 days, using Advanced Row Compression:

```
ALTER TABLE employee ILM ADD POLICY ROW STORE COMPRESS ADVANCED ROW AFTER 3 DAYS OF NO MODIFICATION;
```

In addition to Smart Compression, other ADO policy actions can include data movement to other storage tiers, including lower cost storage tiers or storage tiers with other compression capabilities such as Hybrid Columnar Compression (HCC). HCC requires the use of Oracle Storage—Exadata, Pillar Axiom or Sun ZFS Storage Appliance (ZFSSA).

In this example, a tablespace-level ADO policy automatically moves the table to a different tablespace when the tablespace currently containing the object meets a pre-defined tablespace fullness threshold:

```
ALTER TABLE employee ILM ADD POLICY tier to ilmtbs;
```

Another option when moving a segment to another tablespace is to set the target tablespace to READ ONLY after the object is moved. This is useful for historical data during database backups, since subsequent full database backups will skip READ ONLY tablespaces.

Data Compression

Oracle is a pioneer in database compression technology. More than a decade ago, Oracle Database 9i Release 2 introduced Basic Table Compression which compresses data that is loaded using bulk load operations.

In 2007, Oracle Database 11g Release 1 introduced OLTP Table compression, now called Advanced Row Compression, which maintains compression during all types of data manipulation operations, including conventional DML such as INSERT and UPDATE. In addition, Advanced Row Compression minimizes the overhead of write operations on compressed data, making it suitable for transactional / OLTP environments as well as Data Warehouses, extending the benefits of compression to all application workloads.

Basic Table Compression is a feature of Oracle Database 12c Enterprise Edition (EE). Advanced Row Compression is a part of the Oracle Advanced Compression option.
Advanced Row Compression

Advanced Row Compression uses a unique compression algorithm specifically designed to work with OLTP applications. The algorithm works by eliminating duplicate values within a database block, even across multiple columns. Compressed blocks contain a structure called a symbol table that maintains compression metadata. When a block is compressed, duplicate values are eliminated by first adding a single copy of the duplicate value to the symbol table. Each duplicate value is then replaced by a short reference to the appropriate entry in the symbol table.

Through this innovative design, compressed data is self-contained within the database block, as the metadata used to translate compressed data into its original state is stored in the block header. When compared with competing compression algorithms that maintain a global database symbol table, Oracle’s approach offers significant performance benefits by not introducing additional I/O when accessing compressed data.

Benefits of Advanced Row Compression

The compression ratio achieved in a given environment depends on the data being compressed, specifically the cardinality of the data. In general, organizations can expect to reduce their storage space consumption by a factor of 2x to 4x by using Advanced Row Compression. That is, the amount of space consumed by uncompressed data will be two to four times larger than that of the compressed data.

The benefits of Advanced Row Compression go beyond just on-disk storage savings. One significant advantage is Oracle’s ability to read compressed blocks directly, in memory, without uncompressing the blocks. This helps improve performance due to the reduction in I/O, and the reduction in system calls related to the I/O operations. Further, the buffer cache becomes more efficient by storing more data without having to add memory.

Minimal Performance Overhead

As described above, Advanced Row Compression has no adverse impact on read operations. There can be additional work performed while writing data, making it impossible to completely eliminate performance overhead for write operations. There are several optimizations which minimize this overhead for Advanced Row Compression. Oracle Database compresses blocks in batch mode rather than compressing data every time a write operation takes place. A newly initialized block remains uncompressed until data in the block reaches an internally controlled threshold. When a transaction causes the data in the block to reach this threshold, all contents of
the block are compressed. Subsequently, as more data is added to the block and the threshold is again reached, the entire block is recompressed to achieve the highest level of compression.

This process repeats until Oracle determines that the block can no longer benefit from further compression. Only the transaction that performs the compression of the block will experience the slight compression overhead – the majority of DML transactions on compressed blocks will have the exact same performance as they would with uncompressed blocks.

Figure 2: Advanced Row Compression Process

Performance Examples: Table Scan/DML Performance Results:
ERP Database’s 10 Largest Tables (Source: Oracle)
Advanced Row Compression Migration and Best Practices

For new tables and partitions, enabling Advanced Row Compression is easy: simply CREATE the table or partition and specify “ROW STORE COMPRESS ADVANCED”. See the example below:

```sql
CREATE TABLE emp (emp_id NUMBER, first_name VARCHAR2(128), last_name VARCHAR2(128)) ROW STORE COMPRESS ADVANCED;
```

For existing tables and partitions, there are three recommended approaches to enabling Advanced Row Compression:

1. **ALTER TABLE … ROW STORE COMPRESS ADVANCED**
   - This approach will enable Advanced Row Compression for all future DML -- however, the existing data in the table will remain uncompressed.

2. **Online Redefinition (DBMS_REDEFINITION)**
   - This approach will enable Advanced Row Compression for future DML and also compress existing data. Using DBMS_REDEFINITION keeps the table online for both read/write activity during the migration. Run DBMS_REDEFINITION in parallel for best performance.
   - Online redefinition will clone the indexes to the interim table during the operation. All the cloned indexes are incrementally maintained during the sync (refresh) operation so there is no interruption in the use of the indexes during, or after, the online redefinition. The only exception is when online redefinition is used for redefining a partition -- any global indexes are invalidated and need to be rebuilt after the online redefinition.

3. **ALTER TABLE … MOVE ROW STORE COMPRESS ADVANCED**
   - This approach will enable Advanced Row Compression for future DML and also compress existing data. While the table is being moved it is online for read activity but has an exclusive (X) lock -- so all DML will be blocked until the move command completes. Run ALTER TABLE…MOVE in parallel for best performance.
   - ALTERNATE TABLE…MOVE will invalidate any indexes on the partition or table; those indexes will need to be rebuilt after the ALTER TABLE…MOVE. For partition moves, the use of ALTER TABLE…MOVE PARTITION with the UPDATE INDEXES clause will maintain indexes (it places an exclusive (X) lock so all DML will be blocked until the move command completes) – not available for non-partitioned tables.

   - ALTERNATE TABLE…MOVE PARTITION ONLINE allows DML operations to continue to run uninterrupted on the partition that is being moved. Global indexes are maintained during the move partition operation, so a manual index rebuild is no longer required. Certain uses of Online Move Partition require Advanced Compression: specifically, if the user uses the feature to move a partition to a compressed format (any form of compression, including Basic, Advanced Row, or HCC), then an Oracle Advanced Compression option license is required.

   - The ALTERNATE TABLE…MOVE statement allows you to relocate data of a non-partitioned table, or of a partition of a partitioned table, into a new segment, and optionally into a different tablespace. ALTERNATE TABLE…MOVE ROW STORE COMPRESS ADVANCED compresses the data by creating new extents for the compressed data in the tablespace being moved to -- it is important to note that the positioning of the new segment can be anywhere within the data file, not necessarily at the tail of the file or head of the file. When the original segment is released, depending on the location of the extents, it may or may not be possible to shrink the data file.
Below are some best practices and considerations for the capabilities that are included as part of the Oracle Advanced Compression option:

- The general recommendation is to compress all the tables in the database with one exception: if the table is used as a queue, i.e. rows are inserted into the table, then later most or all of the rows are deleted, then more rows are inserted then deleted, then you shouldn't compress the table.

- The best test environment for each Advanced Compression capability is where you can most closely duplicate the production environment—this will provide the most realistic (pre- and post-compression) performance and functionality comparisons.

- Space usage reduction with Advanced Row Compression gives the best results where the most duplicate data is stored (low cardinality). This is especially true for backups—greater compression will result in less data backed up and hence shorter recovery time. Sorting data (on the columns with the most duplicates) prior to bulk loads may increase the compression ratio.

- Regarding whether or not to compress at the Tablespace level: For custom applications, we recommend compressing at the Tablespace level, but users should consider turning off compression on very high traffic or very small tables, such as tables used as queues. For commercial packaged applications, where typically the number of objects can be very large, the recommended approach is object selection instead of exclusion. Often the top hundred largest tables and indexes consume the majority of the database space. Compressing those objects, while excluding high traffic objects like tables used as queues, will give the majority of the compression benefits. Other objects can be compressed over time as needed.

- Prefix compression (index) is included with Oracle Database Enterprise Edition at no extra cost—it does not require licensing the Oracle Advanced Compression option.

- Although CPU overhead is typically minimal, implementing Advanced Row Compression is ideal on systems with available CPU cycles, as compression will have additional, although minor overhead for some DML operations.

- Compression Advisor is a PL/SQL package that is used to estimate potential storage savings, for Advanced Row Compression, based on analysis of a sample of data. It provides a good estimate of the actual compression ratio that will be obtained after implementing Advanced Row Compression. A version of Compression Advisor, which supports Oracle Database 9i Release 2 through 11g Release 1, is available for free on the Oracle Technology Network website. Compression Advisor (DBMS_COMPRESSION) is built in to Oracle Database 11g Release 2 and above.

- Advanced Row Compression is NOT supported for use with tables that have LONG data types.

- Larger blocks don’t always ensure higher Advanced Row Compression ratios. Testing with your own data is suggested if you want to determine if larger/smaller block sizes will have an impact on your Advanced Row Compression ratio.

- LOBs are best stored in SecureFiles, and if the customer has licensed the Oracle Advanced Compression option, they can use Advanced LOB Compression and Deduplication to potentially reduce the amount of storage required for LOBs.

- Data Pump compression is completely independent of Advanced Row Compression. The Data Pump dumpfile is uncompressed inline during the import process, and the data is then imported into the target table based on the compression characteristics of the table. Data Pump compression is licensed only on the export side—a compressed data pump export dump can be imported into a database that is not licensed for compression. This allows users to export using data pump compression to decrease dumpfile size, and then import into uncompressed tables in databases where compression is not licensed.

- If users need more flexibility in tailoring an ADO policy, they can do so with a custom ADO policy. Custom ADO policies utilize a user provided function to evaluate each applicable segment.

- It is sometimes necessary to move data as quickly as possible from one tier to another and it is not possible to wait until the next maintenance window. The ability to execute ADO policies immediately provides the ability to move or compress data on demand, regardless of any existing policies.
Compression for Unstructured Data

SecureFiles offers a ‘best-of-both-worlds’ architecture for storing unstructured content such as documents, images, spreadsheets and XML files and is specifically engineered to deliver high performance for file data equal to or better than traditional file systems, while retaining the advantages of Oracle Database.

SecureFiles is designed as a superset of the ANSI standard LOB data type and offers easy migration from existing BasicFiles LOBs, the precursor to SecureFiles. With SecureFiles, organizations can manage all relational data and associated file data with Oracle Database using a single security/audit model, a unified backup & recovery process and perform seamless retrievals across all information.

The Oracle Advanced Compression option includes Advanced LOB Compression and Deduplication features that can dramatically reduce the storage footprint of SecureFiles data, while also improving performance.

Advanced LOB Deduplication

It is extremely common for applications to store exact replicas of files. A typical example is an email application where multiple users may receive the same attachment. Advanced LOB De-duplication eliminates duplicate copies of SecureFiles data. Oracle Database stores one image of the SecureFiles data and replaces the duplicate copies with references to this image.

Consider an email application where 10 users receive an email with the same 1MB attachment. Without Advanced LOB Deduplication, the system would store one copy of the file for each of the 10 users – requiring 10MB of storage. If the email application in our example uses Advanced LOB Deduplication, it will store the 1MB attachment just once. That’s a 90% savings in storage requirements.

In addition to the storage savings, Advanced LOB Deduplication also increases application performance. Specifically, write and copy operations are much more efficient since only references to the SecureFiles data are written. Further, read operations may improve if duplicate SecureFiles data already exists in the buffer cache.

Advanced LOB Compression

Advanced Compression provides another mechanism to control the size of your SecureFiles data. Advanced LOB Compression utilizes industry standard compression algorithms to further minimize the storage requirements of SecureFiles data.

With Advanced LOB Compression, files such as documents or XML files experience a reduction of 2x to 3x times in size. Advanced LOB Compression automatically avoids compressing data that would not benefit from compression – for instance a document that was compressed via a 3rd party tool before being inserted into the database as a SecureFiles file. Applications are still able to perform random reads and writes on compressed SecureFiles data since the compressed data is internally broken down into small chunks of data. This can vastly improve performance when compared with compressing entire files before inserting them into the database.
There are three levels of Advanced LOB Compression: LOW, MEDIUM, and HIGH. By default, Advanced LOB Compression uses the MEDIUM level, which typically provides good compression with a modest CPU overhead of 3-5%. Advanced LOB Compression LOW is optimized for high performance. Advanced LOB Compression LOW maintains about 80% of the compression achieved through MEDIUM, while utilizing 3x less CPU. Finally, Advanced LOB Compression HIGH achieves the highest storage savings but incurs the most CPU overhead.

For more information about SecureFiles and LOB storage, please see the Oracle® Database SecureFiles and Large Objects Developer's Guide.

Compression for Backup Data

In addition to compressing data stored inside the database, Advanced Compression also includes the capability to compress backed up data. Recovery Manager (RMAN) and Data Pump are the two most commonly used tools to backup the data stored inside an Oracle Database.

RMAN makes a block-by-block backup of the database data, also known as a “physical” backup, which can be used to perform database, tablespace or block level recovery. Data Pump is used to perform a “logical” backup by offloading data from one or more tables into a flat file.

Advanced Compression includes the capability to compress the backup data generated by both of these tools.

Recovery Manager (RMAN) Compression

The continuous growth in enterprise databases creates an enormous challenge to database administrators. The storage requirements for maintaining database backups and the performance of the backup procedures are directly impacted by database size. Advanced Compression includes RMAN compression technology that can dramatically reduce the storage requirements for backup data.

Due to RMAN’s tight integration with Oracle Database, backup data is compressed before it is written to disk or tape and doesn’t need to be uncompressed before recovery – providing an enormous reduction in storage costs and a potentially large reduction in backup and restore times.

There are three levels of RMAN Compression: LOW, MEDIUM, and HIGH. The amount of storage savings increases from LOW to HIGH, while potentially consuming more CPU resources.

Data Pump Compression

The ability to compress the metadata associated with a Data Pump job was first provided in Oracle Database 10g Release 2. In Oracle Database 11g, this compression capability was extended so that table data can be compressed on export; this extended capability is part of the Oracle Advanced Compression option.

Data Pump compression is an inline operation, so the reduced dump file size means a significant savings in disk space. Unlike operating system or file system compression utilities, Data Pump compression is fully inline on the import side as well, so there is no need to decompress a dump file before importing it. The compressed dump file sets are automatically decompressed during import without any additional steps by the Database Administrator.

Full Data Pump functionality is available using a compressed file. Any command that is used on a regular file will also work on a compressed file. The following options are used to determine which parts of a dump file set should be compressed:

- **ALL** enables compression for the entire export operation.
- **DATA-ONLY** results in all data being written to the dump file in compressed format.
METADATA-ONLY results in all metadata being written to the dump file in compressed format. This is the default.

NONE disables compression for the entire export operation.

An expdp command-line option for Oracle Data Pump Export can be used to control the degree of compression used (BASIC, LOW, MEDIUM or HIGH) for an Oracle Data Pump dump file – the same options can also be specified to the PL/SQL DBMS_DATAPUMP package.

The higher the degree of compression, the higher the latency incurred but the better compression ratio achieved. That is, the HIGH option will likely incur more overhead, but should compress the data better. These options enable the DBA to trade off time spent compressing data against the size of the Oracle Data Pump dump file -- the use of the LOW, MEDIUM and HIGH options require the Oracle Advanced Compression option.

The reduction in dump file size will vary based on data types and other factors. Note that when importing using Data Pump, the CREATE TABLE statements will have compression clauses that match the definition in the export file. If a compression clause is missing, then the table inherits the COMPRESSION attributes of the tablespace where the table is stored.

For more information about Oracle Data Pump, please visit http://www.oracle.com/technetwork/database/enterpri-se-edition/index-093639.html

Advanced Index Compression

Indexes are used extensively inside OLTP databases since they are capable of efficiently supporting a wide variety of access paths to the data stored in relational tables. It is very common to find a large number of indexes being created on a single table to support the multitude of access paths for OLTP applications, this can cause indexes to contribute a greater share to the overall storage of a database when compared to the size of the base tables alone.

Advanced Index compression is a new form of index block compression. Creating an index using Advanced Index Compression reduces the size of all supported unique and non-unique indexes -- while still providing efficient access to the indexes. Advanced Index Compression works well on all supported indexes, including those indexes that are not good candidates (indexes with no duplicate values, or few duplicate values, for given number of leading columns of the index) with the existing index Prefix Compression feature (see below).

Advanced Index Compression works at the block level to provide the best compression for each block, this means that users don't need knowledge of data characteristics – Advanced Index Compression automatically chooses the right compression per block. The use of Advanced Index Compression requires the Oracle Advanced Compression option.

The following is an example of enabling Advanced Index Compression during the creation of the hr.emp_mndp_ix index:

```
CREATE INDEX hr.emp_mndp_ix ON hr.employees(manager_id, department_id) COMPRESS ADVANCED LOW;
```

Advanced Network Compression

Advanced Network Compression, also referred to as SQL Network Data Compression, can be used to compress the network data to be transmitted at the sending side and then uncompress it at the receiving side to reduce the network traffic. Advanced Network Compression reduces the size of the session data unit (SDU) transmitted over a data connection. Reducing the size of data reduces the time required to transmit the SDU.
The benefits of Advanced Network Compression include:

- **Increased effective network throughput**: Compression allows transmission of large data in less time. SQL query response becomes faster due to the reduced transmission time. Constrained bandwidth environments can utilize this to reduce query response time.

- **Reduced bandwidth utilization**: Compression saves bandwidth by reducing the data to be transmitted, allowing other applications to use the freed-up bandwidth. This also helps in reducing the cost of providing network bandwidth.

Advanced Network Compression not only makes SQL query responses faster but also saves bandwidth. On narrow bandwidth connections, with faster CPU, it could significantly improve performance. The compression is transparent to client applications.

**Data Guard Redo Transport Compression**

Oracle Data Guard provides the management, monitoring and automation software infrastructure to create, maintain, and monitor one or more standby databases to protect enterprise data from failures, disasters, errors and data corruptions. Data Guard maintains synchronization of primary and standby databases using redo data (the information required to recover a transaction). As transactions occur in the primary database, redo data is generated and written to the local redo log files.

Data Guard Redo Transport Services are used to transfer this redo data to the standby site(s). With Advanced Compression, redo data may be transmitted in a compressed format to reduce network bandwidth consumption and in some cases reduce transmission time of redo data. Redo data can be transmitted in a compressed format when the Oracle Data Guard configuration uses either synchronous redo transport (SYNC) or asynchronous redo transport (ASYNC).

For more information about Oracle Data Guard, please visit http://www.oracle.com/technetwork/database/features/availability/dataguardoverview-083155.html

**Optimization for Flashback Data Archive History Tables**

Flashback Data Archive (FDA) was introduced in Oracle Database 11g Release 1; it automatically tracks changes to specified tables at the row level, creating a row level history. It also automatically tracks schema changes to specified tables. A key feature of FDA is the ability to do transaction time temporal SQL queries - using the simple and powerful Flashback Query feature of the database to perform queries on historical data.

The volume of data that FDA generates as history can be large; to optimize the storage and performance of this data, Advanced Compression enables FDA to utilize Advanced Row Compression, Advanced LOB Compression and Deduplication and Compression Tiering -- which are not available by default for FDA history tables.

With Advanced Compression, FDA provides the ability to enable or disable optimized data at the flashback archive level, and is available for both CREATE FLASHBACK ARCHIVE and ALTER FLASHBACK ARCHIVE.

**Storage Snapshot Optimization**

While Recovery Manager (RMAN) remains the most popular method to perform Oracle Database backups, another method for taking database backups is to create a storage snapshot of all of the files in the database (data files, control files, and online redo logs), mount that snapshot on a different system than the one that runs the production database, and copy the data to tertiary storage, such as tape, from that second system.

Snapshots taken this way are “crash-consistent”, provided the storage product adheres to specific guidelines outlined in Oracle documentation. If such a snapshot is restored, Oracle cannot distinguish between that and a database that crashed at the moment the snapshot was taken. Crash-consistent backups can be opened and used after undergoing standard crash (i.e. instance) recovery. However, they cannot be reliably used for point-in-time recovery, as the redo logs do not contain sufficient information for media recovery to remove the data files’ inconsistency (since the database was open for writes when snapshot was taken). To perform point-in-time recovery, one must adhere to the requirements and strictly follow the manual procedures as outlined in Support Note 604683.1.
Alternatively, snapshots taken in backup mode, i.e. ALTER DATABASE [BEGIN | END] BACKUP, remove the point-in-time recovery restriction, as additional information is written into the redo logs to remove the data files' inconsistency upon recovery. Since each database needs to be placed in this mode before snapshot is taken and taken out of this mode when the snapshot completes - this complexity is magnified when this procedure must be done for tens, hundreds, or thousands of databases. In addition, during this mode, whole block images are written to redo logs as they are changed, inducing additional I/O activity - this overhead is magnified when you have many databases running on the same array.

With the Oracle Database 12c RECOVER .. SNAPSHOT TIME command, available with Advanced Compression, storage snapshots taken without the database in backup mode can be recovered in one step, whether to the current time or a specific point-in-time after the snapshot was taken, without any additional procedures. By supporting all types of recovery operations using these snapshots, this optimization effectively eliminates the need for backup mode and its associated complexity and overhead, freeing the DBA's time to focus on more critical production tasks.

Hybrid Columnar Compression Row Level Locking

Hybrid Columnar Compression (HCC) technology is a method for organizing data within a set of database blocks. HCC utilizes a combination of both row and columnar methods for storing data. A logical construct, called the Compression Unit (CU), is used to store a set of HCC-compressed data. When data is loaded, groups of rows are stored in columnar format, with the values for a given column stored and compressed together. After the column data for a set of rows has been compressed, it is fit into the compression unit.

Hybrid Columnar Compression uses one lock per CU. Optionally, users can choose to enable Row Level Locking for Compression Units -- the use of HCC Row level Locking requires the Oracle Advanced Compression option and is only available on Exadata storage. The default with HCC is NO ROW LEVEL LOCKING, ROW LEVEL LOCKING is explicitly specified during a CREATE TABLE or ALTER TABLE MOVE operation.

The following is an example of enabling HCC Row Level Locking:

```sql
... COMPRESS FOR [compression_type] [ROW LEVEL LOCKING | NO ROW LEVEL LOCKING]
```

Exadata Flash Cache Compression

Exadata Flash Cache compression dynamically increases the logical capacity of the flash cache by transparently compressing user data as it is loaded into the flash cache. This allows much more data to be kept in flash, and decreases the need to access data on disk drives. The I/Os to data in flash are orders of magnitude faster than the I/Os to data on disk. The compression and decompression operations are completely transparent to the application and database, and have no performance overhead, even when running at rates of millions of I/Os per second.

Depending on the user data compressibility, Oracle Exadata Storage Server Software dynamically expands the flash cache size up to two times. Compression benefits vary based on the redundancy in the data. Tables and indexes that are uncompressed have the largest space reductions. Tables and indexes that are OLTP Table compressed have significant space reductions. Tables that use Hybrid Columnar Compression have minimal space reductions. This feature can be enabled only on an Exadata storage platform and all database processors that access the Exadata storage platform must be licensed for Oracle Advanced Compression.

Minimum hardware: Exadata Storage Server with Sun Server X4-2L Servers. Minimum software: Oracle Exadata Storage Server Software release 11.2.3.3

Online Move Partition (to any compressed format)

ALTER TABLE ... MOVE PARTITION ONLINE allows DML operations to continue to run uninterrupted on the partition that is being moved. Global indexes are maintained during the move partition, so a manual index rebuild is no longer required.
Certain uses of Online Move Partition require Advanced Compression: specifically, if the user uses the feature to move a partition to a compressed format (any form of compression, including Basic, Advanced Row or Hybrid Columnar Compression), then an Oracle Advanced Compression option license is required.

Out-of-the-Box Compression Capabilities

Oracle Database 12c Enterprise Edition includes a number of compression capabilities, out-of-the-box, that do not require separate licenses; these include:

**Hybrid Columnar Compression with Oracle Storage (Pillar Axiom and ZFSSA)**

Hybrid Columnar Compression (HCC) technology is a method for organizing data within a set of database blocks. HCC utilizes a combination of both row and columnar methods for storing data.

A logical construct, called the compression unit, is used to store a set of HCC-compressed data. When data is loaded, groups of rows are stored in columnar format, with the values for a given column stored and compressed together. After the column data for a set of rows has been compressed, it is fit into the compression unit.

Storing column data together, with the same data type and similar characteristics, dramatically increases the storage savings achieved from compression, typical HCC compression ratios range from 6x to 15x, depending on the type of HCC compression used.

Hybrid Columnar Compression, initially only available on Exadata, has been extended to support Pillar Axiom and Sun ZFS Storage Appliance (ZFSSA) storage when used with Oracle Database Enterprise Edition 11.2.0.3 and above.

**Basic Table Compression**

Oracle Database 9i introduced Basic Table Compression more than a decade ago, which compresses data that is loaded using bulk load operations. Basic Table Compression is a feature of Oracle Database Enterprise Edition (EE).

Unlike Advanced Row Compression, Basic Compression does not apply compression to DML operations (INSERT/UPDATE) performed on the table after the initial bulk load. The formats on disk for Basic Compression and Advanced Row Compression are identical, so it is technically possible to convert from Basic to Advanced Row Compression simply by changing the storage definition on the table/partition.

**RMAN Basic Compression**

Oracle Recovery Manager (RMAN) includes a Basic Compression capability which enables RMAN to perform binary compression of backup sets.

**Data Pump Metadata Compression**

The COMPRESSION parameter can be used to decrease the size of metadata written during DataPump exports.

---

Index Compression

Index Key compression is a feature of Oracle Database that enables users to compress portions of the primary key column values in an index or index-organized table, which reduces the storage overhead of repeated values.

Key compression breaks the index key into a prefix entry (the grouping piece) and a suffix entry (the unique piece). Compression is achieved by sharing the prefix entries among the suffix entries in an index block.

Only keys in the leaf blocks of a B-tree index are compressed. Key compression is done within an index block but not across multiple index blocks. Indexes can be compressed independently of whether the underlying table data is compressed.

Conclusion

The massive growth in data volume, being experienced by enterprises, introduces significant challenges. Companies must quickly adapt to the changing business landscape without impacting the bottom line. IT managers need to efficiently manage their existing infrastructure to control costs, yet continue to deliver extraordinary application performance.

The Oracle Advanced Compression option and Oracle Database 12c together provide a robust set of compression, performance and data storage optimization capabilities that enable IT managers to succeed in this complex environment.

Using Advanced Compression, enterprises can efficiently manage their increasing data requirements throughout all components of their data center – minimizing CapEx and OpEx costs while continuing to achieve the highest levels of application performance.
