An Oracle White Paper
July 2009

Oracle Fusion Middleware MapViewer 11g
Disclaimer

The following is intended to outline our general product direction. It is intended for information purposes only, and may not be incorporated into any contract. It is not a commitment to deliver any material, code, or functionality, and should not be relied upon in making purchasing decisions. The development, release, and timing of any features or functionality described for Oracle’s products remains at the sole discretion of Oracle.
Introduction

A picture, as they say, is worth a thousand words. This is particularly true when trying to capture the complexity of interactions among people, resources, products, and business processes distributed over geographic space. For many centuries people have relied on maps to capture and simplify these complex relationships, turning them into readily consumable, powerful packages of unambiguous information. Beginning with Oracle Database 10g and Oracle Application Server 10g and now expanded with Oracle Database 11g and the Fusion Middleware products, the basic Oracle platform delivers powerful, universally understood geospatial capabilities to every developer.

Every Oracle Database includes extensive spatial capabilities in the Oracle Locator feature. Oracle Spatial option for Oracle Database Enterprise Edition expands Oracle Locator functionality with support for Geocoding, Routing, and advanced spatial data models to manage topologies, networks, linear referencing, gridded data and georaster imagery. Users can load all types of geometric data into Oracle Database, create spatial indexes, and issue spatial queries through SQL. Because of this, Oracle Database is an industry standard for managing geospatial data.

MapViewer complements the geographic data management capacity of Oracle Database by providing a generic web-based means of delivering and viewing any geospatial data in the database. This creates enormous potential for analyzing and understanding the geographic component(s) of any business, by unlocking the enterprise information in many corporate warehouses and making it available in easy to use mapping applications. For instance, business applications such as Field Service, Transportation and Logistics, Product Lifecycle Management, Human Resources, and Real Estate commonly render and visualize the massive amount of data they control because there is a geographic component such as an address tied to the data. Developers of location-based services, data publishers in state and local government, and architects of web services and more traditional applications can all easily integrate MapViewer into their web-based solutions.

Usage Scenarios

Common use cases include reporting (e.g. sales by region), proximity search (stores or service providers nearby), and analysis (asset locations and condition, and top N insured properties within projected hurricane track). Consequently MapViewer is integrated into enterprise applications such as work and asset management, field service, human capital management, inventory management, and business intelligence dashboards. Similarly it is used in customer facing web sites for store locators, coverage and jurisdiction information, or public works project status and information.
Reporting

A map is often used as a specialized chart or graph type to present information such as regional performance or store locations and their current inventory levels as shown in the Figure 1 and Figure 2 below, respectively.

Figure 1: Regional Performance

Figure 2: Store locations with inventory levels
Proximity Search

The following screenshots (Figure 3 and Figure 4) show the use of maps as a search interface. In both cases the map is used as an interactive UI component for first specifying search criteria and subsequently displaying the search results. In the first example (Figure 3) the user is searching for incidents that occurred within a specific distance from a location (a park) identified by clicking on the map.

![Figure 3: Incidents within a specific distance from a location](image)

The second example shows a summary (aggregate) report of employees at locations within a specified radius from a point clicked on the map.
Figure 4: Summary report of employees within a specified radius

Analysis

The second example above (Figure 4) is also an instance of displaying the results of a spatial analysis query (jobs by category and class within 2 miles of an identified location) on a map. This section includes additional similar examples.

Figure 5 displays the result of a network analysis (traveling salesperson tour) that computes a near optimal tour between specified locations.
Figure 5: Traveling salesperson tour

The screenshot below (Figure 6) shows the result of an Asset Condition Score analysis for a given area of interest. The area of interest in this case is the current map extent or area displayed in the map window. The asset condition score is computed only for those assets (pipelines in this instance) that are within the current map extent.
Figure 6: Asset Condition Score analysis in an area of interest

The next example (Figure 7) shows how multiple metrics may be displayed on a map image. The user selects a section of the gaming establishment’s floor from the layout map on the left and is presented with a heatmap and tabular report on the right. These show a summary report of the cash in, win/loss, and numbers of players at individual machines within the selected area of interest.
Figure 7: Floorplan layout map with heatmap and tabular report

Brief Feature Overview

The MapViewer component in Fusion Middleware is written in Java and runs inside the Oracle Container for J2EE (OC4J) or WebLogic Server (WLS). When it is up and running, MapViewer listens for client requests, which can range from map requests to administrative requests such as defining a data source or listing predefined maps in a data source. All requests will be sent using the HTTP POST method, with the content of the requests encoded in an XML format.

The companion white paper “Oracle Fusion Middleware MapViewer Primer” (http://www.oracle.com/technology/products/mapviewer/mapviewer_training_index.html) and the MapViewer user guide provide further details on the technology and functionality. This section is a very brief overview of Oracle MapViewer functionality.

Since Release 10g Oracle MapViewer includes a new suite of technologies, called Oracle Maps, that consists of a map tile server, a dynamic geospatial query service known as the Feature of Interest (FOI) server, and a Javascript based web mapping client library.

The map tile server automatically fetches and serves cached map image tiles, rendered by Oracle MapViewer or other Web-enabled map providers, to web application clients. The clients can then automatically stitch multiple map image tiles into a seamless large base map. Because the map
image tiles are pre-generated and cached, the application users will experience fast map viewing performance.

The feature of interest server renders spatial feature layers managed by Oracle Spatial, as well as individual geospatial features (points, lines, or polygons) created by an application. Unlike the cached image tiles, which typically represent static content, FOIs are dynamic and represent real-time database or application contents. The dynamic FOIs and the static cached base map enable you to build Web mapping applications.

The JavaScript mapping client is a browser side map display engine that fetches map content from the servers and presents it to client applications. It also provides customizable map-related user interaction control, such as map dragging and clicking, for the application.

The following figure shows the UI of a simple application developed using Oracle Maps.

Figure 8: A Sample Oracle Maps Application

The sample application displays points of interest (airports) on a base map. The map consists of two layers:

- The base map layer displays the ocean, county boundaries, cities, and highways.
- The FOI layer displays airport locations as red dot markers on top of the base map.
In addition to these two layers, a scale bar is displayed in the lower-left corner of the map, and a navigation panel is displayed in the upper-right corner.

The application user can use the mouse to drag the map. When this happens, new image tiles and FOIs are automatically fetched for the spatial region that the map currently covers.

Oracle Maps client applications running inside Web browsers are pure HTML and JavaScript pages that do not require any plug-ins. Therefore, you can build the application using any Web technology that delivers content as pure HTM. Such technologies include JavaServer Pages, Java Servlets, ASP, PHP, and .NET C#. MapViewer 11g comes with over 50 tutorials illustrating various aspects of the new Oracle Maps functionality.

Besides the basic functionality of high performance interactive rendering of geospatial content stored in an Oracle database there are interfaces that help developers extend and enhance MapViewer. Some of them are:

- **Custom Map Tile Provider interface**
  The Oracle Maps API provides a generic get map tile interface. This lets developers use map tiles from a 3rd party provider (such as DigitalGlobe) in their MapViewer application. So the base map or imagery could come from an external online service while the user or application specific content (e.g. Features of Interest) are retrieved from an Oracle database.

- **Custom (external) Attribute Data Provider Support**
  MapViewer now supports middle-tier joins of external attribute data (such as sales) with geometries stored in Oracle Spatial, providing even more thematic mapping possibilities.

- **Custom Spatial Data Provider Support**
  MapViewer provides a generic spatial data provider interface. This interface lets developers extend MapViewer to work with file-based data sources such as ESRI shapefiles or other database software that manages geospatial information.

The following section briefly describes MapViewer application development with Oracle tools such as JDeveloper or Application Express (APEX). The subsequent section presents examples of using some of the features outlined above in this section.

**Developing MapViewer Applications**

MapViewer has XML, Java, and Javascript APIs for application development. These, combined with Oracle development tools, make it simple to develop web-mapping applications. There are two technical white papers (one each for the Java and Javascript APIs) titled “Developing Spatial Applications using Oracle Spatial and MapViewer”. Similarly, the how-to note “Integrating Application Express with MapViewer” covers the basics of including web-mapping functionality in an APEX application.

JDeveloper 11g contains a rich feature set reapid application development known as the Application Development Framework (ADF) and associated set of Data Visualization Tools (DVT), or components, such as dials, gauges and charts. ADF includes Java Server Faces
compliant components known as ADF Faces that include data visualization components. The DVT GeoMap component is one of them. It exposes the MapViewer Javascript API functionality and handles all JSF related event, partial page refresh, component communication, synchronization, and other infrastructure services. The following JDeveloper screenshot shows the DVT GeoMap drag-and-drop component listed in the Component Palette menu and the Create Geographic Map dialog that appears at design time.

Examples of Using Specific Features

This section briefly describes how specific features such as the Javascript API and methods to support external data sources may be used in applications. A companion document (“Using MapViewer Interfaces for External Data Sources”) provides technical details (i.e. the specific methods and sample code) and is also available from the MapViewer page on Oracle Technology Network (www.oracle.com/technology/products/mapviewer/).

JavaScript API

The Oracle Maps tutorial, which is part of the MapViewer kit, provides over 40 examples demonstrating the API. The API enables location services application such as the one shown
below. It is a screenshot of the demo application accessible at http://elocation.oracle.com/elocation/ajax/. The screenshot shows the results of a search for points-of-interest (POIs) whose name contains the string “airport” and are located within the current map extent (i.e. Southern California).

Search results can be paginated and linked such that an info-window pops up if the user clicks on a POI name in the list or the POI listing is highlighted if the user clicks on it on the map.

![Search results screenshot]

**Figure 10:** Search for airports in Southern California

**Custom Map Tile Provider**

MapViewer renders geospatial content, such as street networks or satellite imagery, stored in an Oracle database. Sometimes users may prefer to render only application-specific content, such as customer or business partner locations, on background maps or imagery obtained from an external source. An example of this is high-resolution imagery from DigitalGlobe’s online service as shown in the screenshot below.
Oracle Maps example - Custom map tile layer

This demo shows how to display third-party map tiles using Oracle Maps client. Select one from the following tile servers: 

GeoRSS (and web services) Support

MapViewer supports GeoRSS (www.georss.org) and the OpenGeospatial Consortium’s (OGC) Web Feature Server (WFS 1.0) and Web MapServer (WMS 1.3) standards. This allows users to subscribe to a GeoRSS feed and display the locations and associated content on a map. In the example below, the map includes geotagged content such as photos from Flickr, restaurant reviews from Yelp, or Wikipedia articles related to an area around a postal code.
Oracle Maps example - GeoRSS support

Figure 12: Geotagged content including GeoRSS Feeds

External Attribute (non-spatial) Data Provider

Often the data to be displayed on a map does not contain geographic coordinates and may not even be stored in an Oracle database. This data can still be displayed on a map, however, if there is some means of linking or joining it to geospatial data via a common attribute such as a place name, identifier, or street address. MapViewer provides an interface for this purpose. It is commonly used with applications based on the Oracle BI platform or JDeveloper where the data source is not necessarily an Oracle database. It is particularly useful for BI applications when used in conjunction with the JavaScript APIs of both (OBIEE, MapViewer) products.

The document titled “Integrating Oracle Business Intelligence Enterprise Edition with Oracle Fusion Middleware MapViewer” (available on OTN) discusses the technical details. It describes four common integration scenarios: (i) displaying thematic maps in reports, (ii) drilling to a new level of detail on a BI dashboard based on a drill-down or zoom in map interaction, (iii) invoking a detail report for a location or region selected on the map, and (iv) clicking on an item in a different component (such as a Table view) and highlighting the corresponding item on the map.

In the following screenshot the OBIEE Answers platform is mashing up project information, stored in spreadsheets, with a sales territory map based on the sales region name.
Figure 13: Oracle Business Intelligence Enterprise Edition Answers with Oracle MapViewer

The same external attribute, or non-spatial, data provider interface has been used to mashup content from non-Oracle data sources such as Access database, or reports published as XML documents, with Oracle Spatial data and rendered with MapViewer.

Conclusion

MapViewer provides web application developers a versatile means to integrate and visualize business data with maps. It uses the basic capability included with Oracle10g (either Oracle Spatial or Locator) to manage geographic mapping data. It hides the complexity of spatial data queries and the cartographic rendering process from application developers. They can easily integrate MapViewer into their applications. This creates enormous potential for understanding and capturing the geographic component(s) of any business, by unlocking the enterprise information in many corporate warehouses and making it available to basic mapping applications.
