Introduction

Oracle Private Cloud Appliance is a converged infrastructure solution that combines preconfigured networking, servers, and storage into a convenient package that system administrators can easily deploy into an existing data center. Each Oracle Private Cloud Appliance arrives in a single rack with up to 25 servers (compute nodes), as well as multiple InfiniBand and Ethernet switches. Oracle Private Cloud Appliance has been designed to scale dynamically using built-in software automation to accommodate the expansion of its server and storage space. Combined with the virtualization power of Oracle VM, Oracle Private Cloud Appliance provides the perfect general-purpose solution for rapidly and easily bringing online a new rack into a cloud environment.

The existing storage within Oracle Private Cloud Appliance is a small Oracle ZFS Storage Appliance (the Oracle ZFS Storage ZS3-ES model), which is located in the bottom of the rack. It contains two clustered 1U controllers and a single disk tray supplied with twenty 900 GB SAS data drives. This design could be limiting for high-performance database workloads as well as for backup and recovery needs. To address these requirements, Oracle Private Cloud Appliance has been qualified for use with an additional external Oracle ZFS Storage Appliance. This document describes how to increase the storage capacity of Oracle Private Cloud Appliance by adding a new rack containing a larger Oracle ZFS Storage Appliance cluster.
Why Use Oracle ZFS Storage Appliance with Oracle Private Cloud Appliance?

Oracle ZFS Storage Appliance is an ideal solution for storage expansion of Oracle Private Cloud Appliance. It has been co-engineered with Oracle Private Cloud Appliance to maximize performance and efficiency while reducing deployment risk and total cost of ownership. As an engineered storage expansion, Oracle ZFS Storage Appliance offers the following capabilities to Oracle Private Cloud Appliance customers:

- Oracle ZFS Storage Appliance provides extremely high performance for applications and workloads deployed on Oracle Private Cloud Appliance. It is optimized for Input/Output Operations per Second (IOPS)-intensive workloads, such as OLTP databases, as well as for bandwidth-driven workloads including data warehousing, business intelligence analytics, and video processing. Oracle ZFS Storage Appliance is powerful enough to run a diverse set of workloads concurrently by leveraging the Oracle Private Cloud Appliance’s InfiniBand network.

- Oracle ZFS Storage Appliance provides high throughput for thousands of virtual machines (VMs). It is capable of booting 16,000 VMs in approximately seven minutes. It provides fast response time and low latency, which allows it to avoid VM boot storms, throughput congestion, hot spots, and I/O saturation.

- Oracle ZFS Storage Appliance also comes with superior storage analytics, which allow customers to visualize and drill down into specific workloads to understand where congestion occurs and why. It can even allow them to examine and manage the storage aspects of Oracle Private Cloud Appliance environments all the way down to the VM level.

- Oracle ZFS Storage Appliance provides scalable capacity for Oracle Private Cloud Appliance customers. It is offered in multiple configurations to address different application needs and can expand up to 3.4 PB.

- Oracle ZFS Storage Appliance reduces risk by automating storage management using Oracle Enterprise Manager, so customers have fewer storage systems to integrate and manage. It also lowers risk by providing leading fault-monitoring and self-healing capabilities, and by simplifying setup and management through its DTrace Analytics feature.

- Oracle ZFS Storage Appliance reduces complexity because its large DRAM and flash cache–based architecture is more efficient in serving the I/O from large virtualized environments. In addition, Oracle Database’s unique Hybrid Columnar Compression feature, when used in conjunction with Oracle Private Cloud Appliance, reduces the amount of storage needed for data warehouses. And, it enables customers to lower total cost of ownership because they need fewer systems that cost less and are easier to manage.

Oracle ZFS Storage Appliance is ideal for expanding Oracle Private Cloud Appliance storage by utilizing the Oracle ZFS Storage Appliance intelligent caching capabilities. This provides the I/O performance of DRAM (1000x faster than flash) at the cost and scalability of a disk-based storage solution.

The following sections outline the steps required for expanding Oracle Private Cloud Appliance using Oracle ZFS Storage Appliance. Either the Oracle ZFS Storage ZS3-4 or ZS3-2 appliance can be utilized depending on the capacity demands of the environment.

Cabling

Oracle Private Cloud Appliance currently supports external connectivity to an Oracle ZFS Storage Appliance cluster using InfiniBand for storage data traffic. Additional Ethernet connections should also be made between the Oracle ZFS Storage Appliance cluster and an Ethernet switch connected to a customer’s network infrastructure. The two Oracle Switch ES1-24 switches located in U21 of the Oracle Private Cloud Appliance should not be used for Oracle ZFS Storage Appliance connectivity.
Management

The network management port on both Oracle ZFS Storage Appliance controllers should be connected to a customer-provided Ethernet switch. NET0 on both controllers should also be connected to this switch for a total of four connections.

InfiniBand

Four InfiniBand connections should be made between the two Oracle ZFS Storage Appliance controllers and two Oracle Fabric Interconnect F1-15 switches. These connections must be diversified to avoid a single point of failure. Figure 2 illustrates which ports should be utilized on the switches and their paths to the Oracle ZFS Storage Appliance controllers.
Oracle ZFS Storage Appliance supports both an active/active and an active/passive cluster configuration. The configurations slightly differ in their network and storage layouts. An active/active configuration provides the highest performance, while an active/passive configuration provides the most stable and predictable environment during a storage failover event.

Oracle Integrated Lights Out Manager (Oracle ILOM) Configuration

On both controllers, a serial connection must be made to the RJ-45 serial management port. Serial access should use the following settings:

» 9600 baud rate
» 8N1: Eight data bits, no parity, one stop bit
» No flow control, no hardware control, no software control

Once a connection has been established, log in to the console on each Oracle ZFS Storage Appliance controller using username root and password changeme.
Next, use the following commands to set up the Oracle ILOM network interfaces:

```bash
-> cd /SP/network
-> set pendingipaddress=192.168.150.100
    Note: This is an example IP address. Oracle Private Cloud Appliance customers should provision an address within their own network for this connection.
-> set pendingipnetmask=255.255.255.0
-> set pendingipgateway=192.168.150.1
    Note: This is an example gateway address. Oracle Private Cloud Appliance customers should provide their own gateway address.
-> set commitpending=true
```

After completion, ping each Oracle ILOM interface using any compute node on Oracle Private Cloud Appliance to verify that the interfaces are working correctly.

Management Interfaces

Create a VNIC and its management interface for each controller. Next, set default routes, configure services, and set up clustering.

1. Log in to the Oracle ZFS Storage Appliance console through Oracle ILOM.
   The default username is root and the password is changeme.

2. Before clustering can be set up, reset each Oracle ZFS Storage Appliance controller to its factory conditions by issuing the following command from the CLI on each controller:
   ```
   ZFS:> maintenance system factoryreset
   ```

3. After both controllers have rebooted, log in to the console of Oracle ZFS Storage Appliance controller 1 and enter a new password in the Setup screen. Do not enter networking information now; it will be entered later.

4. Create a VNIC for each controller:
   ```
   ZFS:maintenance system setup net> datalinks
datalinks> vnic
datalinks> set links=ixgbe0
   ```
   ```
   Note: Use ixgbe0 for an Oracle ZFS Storage ZS3-2 controller or igb0 for an Oracle ZFS Storage ZS3-4 controller.
   ```
   ```
   datalinks> commit
datalinks> vnic
datalinks> set links=ixgbe0
datalinks> commit
   ```

5. Create the management interface for each VNIC:
   ```
   ZFS:maintenance system setup net datalinks> cd ..
   net> interfaces
   interfaces> ip
   ip> set links=vnic1
   ip> set v4addrs=ip_address_zfs_1/subnet_mask
   ```
Example: `set v4addrs=192.168.150.100/24`

```
ip> commit
interfaces> ip
ip> set links=vnic2
ip> set v4addrs=ip_address_zfs_2/subnet_mask
ip> commit
```

6. Destroy any system-created interfaces:

```
interfaces> destroy ixgbe0
```

**Note:** Use `ixgbe0` for an Oracle ZFS Storage ZS3-2 controller or `igb0` for an Oracle ZFS Storage ZS3-4 controller.

7. Create default routes for both management interfaces using a customer-supplied gateway address:

```
ZFS:maintenance system setup net interfaces> cd ..
net> routing
routing> create
routing> set destination=0.0.0.0
routing> set mask=0
routing> set gateway=gateway_ip_address
routing> set interface=vnici
routing> set family=IPv4
routing> commit
routing> create
routing> set destination=0.0.0.0
routing> set mask=0
routing> set gateway=gateway_ip_address
routing> set interface=vnici2
routing> set family=IPv4
routing> commit
routing> done
net> done
```

8. Set up DNS using a customer-supplied DNS server:

```
ds> set domain=domain_name
dns> set servers=dns_ip_address
dns> done
```

9. Set up NTP using a customer-supplied NTP server:

```
ntp> set servers=ntp_ip_address
ntp> commit
ntp> done
```

10. Set up any needed AD, LDAP, or NIS server, or else type the following command:

```
directory> done
```

11. Bypass the storage setup for now:

```
storage> done
```

12. Set up “Phone Home” capability for Oracle Support:

```
support> scrk
scrk> set soa_id=oracle_support_username
scrk> set soa_password=password
scrk> done
```
13. Configure clustering:

```
ZFS: > configuration cluster setup
cabling> done
identity> set nodename=zfs_2_hostname
identity> set password=changeme
identity> done
```

14. Assign the second VNIC to the second Oracle ZFS Storage Appliance controller:

```
ZFS: > configuration cluster resources
resources> select net/vnic2
net/vnic2> set owner=zfs_2_hostname
net/vnic2> commit
resources> commit
```

15. If an active/active cluster configuration is desired, type Y at the prompt to failback—otherwise, choose N.

Data Interfaces

The storage data interfaces should be created using InfiniBand ports ibp0 and ibp1 on Oracle ZFS Storage Appliance. The network layout will differ based on the cluster configuration chosen in the previous section.

Active/Passive Cluster

1. Create a partition key of ffff for each InfiniBand device:

```
ZFS: > configuration net datalinks partition
partition> set links=ibp0
partition> set pkey=ffff
partition> set linkmode=cm
partition> commit
datalinks> partition
partition> set links=ibp1
partition> set pkey=ffff
partition> set linkmode=cm
partition> commit
```

2. Create an interface on each datalink:

```
ZFS: > configuration net datalinks cd ..
net> interfaces
interfaces> ip
ip> set links=pffff_ibp0
ip> set v4addrs=0.0.0.0/8
ip> commit
interfaces> ip
ip> set links=pffff ibp1
ip> set v4addrs=0.0.0.0/8
ip> commit
```

3. Build an IPMP group using both interfaces with two virtual IP addresses:

```
ZFS: > configuration net interfaces ipmp
ipmp> set links=pffff_ibp0,pffff ibp1
ipmp> set v4addrs=192.168.40.242/24,192.168.40.243/24
ipmp> commit
```
Active/Active Cluster

1. Create a partition key of ffff for each InfiniBand device:

   ZFS1:
   ```bash
   configuration net datalinks partition
   partition> set links=ibp0
   partition> set pkey=ffff
   partition> set linkmode=cm
   partition> commit
   ```

   ZFS2:
   ```bash
   configuration net datalinks partition
   partition> set links=ibp1
   partition> set pkey=ffff
   partition> set linkmode=cm
   partition> commit
   ```

2. Create an interface on each datalink:

   ZFS1:
   ```bash
   configuration net datalinks
   cd ..
   net>
   interfaces
   interfaces>
   ip
   ip> set links=pffff_ibp0
   ip> set v4addr=192.168.40.242/24
   ip> commit
   ```

   ZFS2:
   ```bash
   configuration net interfaces
   ip
   ip> set links=pffff_ibp1
   ip> set v4addr=192.168.40.243/24
   ip> commit
   ```

Pool Setup

Regardless of the cluster configuration, the following storage pool configuration should be used when creating new pools inside of Configuration → Storage:

» Mirrored or RAIDZ1 storage data profile
   » Choose mirrored for high-performance workloads, such as Oracle Database or Oracle VM.
   » Choose RAIDZ1 for streaming or backup workloads, such as Oracle Recovery Manager.

» Striped write log devices

» Striped read cache

» Single pool for active/passive configurations

» Two pools for active/active configurations, one per controller
NFS

Oracle VM requires either NFS or iSCSI for protocol connectivity. Only one protocol should be chosen. The following steps outline the NFS configuration on Oracle ZFS Storage Appliance. Refer to the next section if iSCSI is more desirable.

1. Create a project called “VCA”:
   ```
   ZFS:> shares project VCA
   ```
2. Set the default user and group to root:
   ```
   VCA> set default_group=root
   VCA> set default_user=root
   ```
3. Ensure root access is available to all the Oracle Private Cloud Appliance subnets:
   ```
   VCA> set
   VCA> set sharenfss="sec=sys,rw=@192.168.4.0/24:@192.168.40.0/24,root=@192.168.4.0/24:@192.168.40.0/24"
   VCA> commit
   ```
4. Create a sample share to be imported to Oracle VM:
   ```
   ZFS:> shares select VCA
   VCA> filesystem testshare
   VCA> commit
   ```
5. Create any additional NFS shares needed to expand Oracle VM’s storage capacity.
6. Repeat this procedure for the second controller if an active/active cluster configuration is being used.

iSCSI

Each compute node on Oracle Private Cloud Appliance has an IQN identifier that must be manually added to Oracle ZFS Storage Appliance.

1. Extract the IQN from a root shell on a Oracle Private Cloud Appliance compute node:
   ```
   # cat /etc/iscsi/initiatorname.iscsi
   InitiatorName=iqn.1988-12.com.oracle:974da248268c
   ```
2. Add the IQN to Oracle ZFS Storage Appliance controller 1:
   ```
   ZFS:> configuration san iscsi initiators
   initiators> create
   initiator-000> set alias=vca_computenode_hostname
   initiator-000> set initiator=iqn.1988-12.com.oracle:974da248268c
   
   Note: Use the IQN value discovered on the compute node. This is just an example IQN.
   ```
   ```
   initiator-000> commit
   ```
3. Repeat the steps above for every compute node.
4. Create an initiator group and add all the IQNs:
   ```
   initiators> groups
   groups> create
   group-000> set name=VCA
   group-000> set initiators=1qn.1,1qn.2,1qn.3,1qn.4
   
   Note: Use the Tab key to add each IQN value added in Step 2 and Step 3
   ```
   ```
   group-000> commit
   ```
Next, create an iSCSI target and an iSCSI target group for an active/passive cluster, or create two iSCSI targets and two iSCSI target groups for an active/passive cluster.

**Active/Passive Cluster**

1. Create an iSCSI target:

```bash
ZFS:>
configuration san iscsi targets
targets>
create
targets>
set alias=VCA
targets>
set interfaces=ipmp0
targets>
commit
```

2. Create an iSCSI target group with the previously created iSCSI target:

```bash
targets>
groups
groups>
create
group-000>
set name=VCA
group-000>
set targets=iqn_initiator_string
```

**Note:** The IQN value can be discovered using the Tab key with tabbed completion.

```bash
group-000>
commit
```

**Active/Active Cluster**

1. Create an iSCSI target on Oracle ZFS Storage Appliance controller 1:

```bash
ZFS1:>
configuration san iscsi targets
targets>
create
target-000>
set alias=VCA-1
target-000>
set interfaces=ibp0
target-000>
commit
```

2. Create an iSCSI target group with the previously created iSCSI target:

```bash
targets>
groups
groups>
create
group-000>
set name=VCA-1
group-000>
set targets=iqn_initiator_string
```

**Note:** The IQN value can be discovered using the Tab key with tabbed completion.

```bash
group-000>
commit
```

3. Create an iSCSI target on Oracle ZFS Storage Appliance controller 2:

```bash
ZFS2:>
configuration san iscsi targets
targets>
create
target-000>
set alias=VCA-2
target-000>
set interfaces=ibp1
target-000>
commit
```

4. Create an iSCSI target group with the previously created iSCSI target:

```bash
targets>
groups
groups>
create
group-000>
set name=VCA-2
group-000>
set targets=iqn_initiator_string
```

**Note:** The IQN value can be discovered using the Tab key with tabbed completion.

```bash
group-000>
commit
```
Project and LUNs
After creating the initiator and target groups, an Oracle Private Cloud Appliance project and LUNs should be added for Oracle VM to access.

1. Create a project called “VCA”:

   ```
   ZFS:> shares project VCA
   VCA> commit
   ```

2. Create a sample LUN to be imported to Oracle VM:

   ```
   ZFS:> shares select VCA
   VCA> lun testlun
   VCA/testlun> set initiatorgroup=VCA
   VCA/testlun> set targetgroup=VCA
   ```
   **Note:** Use VCA-1 or VCA-2 instead of VCA if an active/active cluster configuration is being used.

   ```
   VCA/testlun> set volsize=1T
   VCA/testlun> commit
   ```

3. Create any additional LUNs needed to expand Oracle VM’s storage capacity.

Oracle VM Configuration
Oracle VM Manager can be accessed by logging into `https://manager-vIP:7002/ovm/console`, where `manager-vIP` is the virtual IP address of the Oracle VM management console.

NFS
1. Select the **Storage** tab.

   ![Selecting the Storage tab](image)
   Figure 3. Selecting the Storage tab

2. Click the **Discover File Server** icon.

   ![Clicking the Discover File Server icon](image)
   Figure 4. Clicking the Discover File Server icon
3. In the window that opens, enter the following and click **Next**:

   **Name:** zfssa_1  
   **Access Host (IP) Address:** 192.168.40.242

![Figure 5. Entering a name and IP address](image1)

4. Move all of the Oracle Private Cloud Appliance compute nodes from the **Available Admin Server(s)** section to the **Selected Admin Server(s)** section. Click **Next**.

![Figure 6. Selecting the servers that can be used for administrative access](image2)
5. Click **Next** in the Select Refresh Servers screen. Oracle Private Cloud Appliance compute nodes do not need to be added.

6. Select the test share presented.

![Selecting the test share](image1.png)

Figure 7. Selecting the test share

7. Click **Finish** to complete.

8. Repeat these steps for Oracle ZFS Storage Appliance controller 2 if an active/active cluster configuration is being used. Use IP address 192.168.40.243 when repeating Step 3.

The Oracle ZFS Storage Appliance should now be found in the File Server directory tree. Its shares can be added as a new storage repository for Oracle VM.

**iSCSI**

1. Select the **Storage** tab.

![Selecting the Storage tab](image2.png)

Figure 8. Selecting the Storage tab

2. Click the **Discover SAN Server** icon.

![Clicking the Discover SAN Server icon](image3.png)

Figure 9. Clicking the Discover SAN Server icon
3. Enter the Oracle ZFS Storage Appliance controller’s host name in the **Name** field and set **Storage Type** to **iSCSI Storage Server**. Click **Next**.

![Figure 10. Entering the Oracle ZFS Storage Appliance controller's host name](image-url)
4. Enter IP address 192.168.40.242 in the **Access Host** field and click **OK**.

![Figure 11. Entering the IP address](image)

5. Move all of the Oracle Private Cloud Appliance compute nodes from the **Available Server(s)** section to the **Selected Server(s)** section. Click **Next**.

![Figure 12. Moving the compute nodes to the Selected Server(s) section](image)
6. Click the **Edit Access Group** icon (pencil) to edit the selected “Default access group.”

![Figure 13. Clicking the Edit Access Group icon](image)

7. Click the **Storage Initiators** tab and move all initiators from the **Available Storage Initiators** section to the **Selected Storage Initiators** section. Click **OK**.

![Figure 14. Moving the initiators to the Selected Storage Initiators section](image)
8. Click **Finish** to complete.

9. Repeat these steps for Oracle ZFS Storage Appliance controller 2 if an active/active cluster configuration is being used. Use IP address 192.168.40.243 when repeating Step 3.

Oracle ZFS Storage Appliance should now be found in the SAN Server directory tree. Its LUNs can be added as a new storage repository for Oracle VM.

![Figure 15. Oracle ZFS Storage Appliance in the SAN Server directory tree](image)

**Additional Use Cases**

Oracle ZFS Storage Appliance can also be used for general-purpose storage with Oracle VM. Table 1 documents the connectivity options and protocols for this integration. Please note that the guest virtual machines of Oracle VM cannot use Oracle ZFS Storage Appliance for general NFS with IP over InfiniBand (IPoIB). This use case should be implemented using 10 GbE.

**TABLE 1: GENERAL-PURPOSE CONNECTIVITY FOR ORACLE VM**

* It is planned that future support in the software will allow compute nodes to use customer-supplied IP addresses.
Expanding Oracle Private Cloud Appliance Using Oracle ZFS Storage Appliance

February 2016

Author: Paul Johnson
