Preface

The Oracle® Linux Virtualization Manager documentation provides information on installing and configuring a virtualization environment that you can use to manage compute, network and storage resources.

Audience

This document is intended for both new and existing users of Oracle® Linux Virtualization Manager. It is assumed that readers are familiar with virtualization and have a general understanding of Windows and UNIX platforms.

Documentation Location

The documentation for this product is available at:

https://docs.oracle.com/en/virtualization/oracle-linux-virtualization-manager/

Conventions

The following text conventions are used in this document:

• **boldface**: Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.

• *italic*: Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.

• `monospace`: Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at https://www.oracle.com/corporate/accessibility/.

Access to Oracle Support for Accessibility

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit https://www.oracle.com/corporate/accessibility/learning-support.html#support-tab.

Diversity and Inclusion

Oracle is fully committed to diversity and inclusion. Oracle respects and values having a diverse workforce that increases thought leadership and innovation. As part of our initiative to build a more inclusive culture that positively impacts our employees, customers, and partners, we are working to remove insensitive terms from our products and documentation. We are also mindful of the necessity to maintain compatibility with our customers’ existing technologies and the need to ensure continuity of service as Oracle's offerings and industry standards evolve. Because of these technical constraints, our effort to remove insensitive terms is ongoing and will take time and external cooperation.
About this document

This document is part of the documentation set for Oracle Linux Virtualization Manager, which is available at https://docs.oracle.com/en/virtualization/oracle-linux-virtualization-manager/.

This documentation set comprises:

**Oracle Linux Virtualization Manager: Release Notes**

This document provides a summary of the new features, changes, fixed bugs, and known issues in the Oracle Linux Virtualization Manager. It contains last-minute information, which may not be included in the main body of documentation.

**Oracle Linux Virtualization Manager: Architecture and Planning Guide**

This document provides an architectural overview of Oracle Linux Virtualization Manager, prerequisites, and planning information for your environment.

**Oracle Linux Virtualization Manager: Getting Started Guide**

This document explains how to install, configure and get started with the Oracle Linux Virtualization Manager. There is an example scenario that covers some of the basic procedures for setting up the environment, such as, adding hosts and storage, creating virtual machines, configuring networks, working with templates, and backup and restore tasks. In addition, there is information on upgrading your engine and hosts as well as deploying a self-hosted configuration.

**Oracle Linux Virtualization Manager: Administration Guide**

This document provides common administrative tasks for Oracle Linux Virtualization Manager. In addition, you will find information on setting up users and groups, configuring high-availability, memory and CPUs, configuring and using event notifications, configuring vCPUs and virtual memory.

In addition to the Oracle Linux Virtualization Manager documentation, you can also refer to the upstream documentation:

- oVirt Documentation
- oVirt 4.3.10 Release Notes

Document generated on: 2021-09-27 (revision: 999)
Chapter 1 Global Configuration

  1.2.10 Managing Account Settings ................................................................................................. 11

For Oracle Linux Virtualization Manager, global configuration options are set from the Configure dialog box. This dialog box is accessed by selecting Administration and then clicking Configure. From the Configure dialog box, you can configure a number of global resources for your virtualization environment, such as users, roles, system permissions, scheduling policies, instance types, and MAC address pools. You can also customize the way in which users interact with resources in the environment and configure options that can be applied to multiple clusters from a central location.

1.1 Administering User Accounts from the Administration Portal

The following tasks describe common user administration tasks that are performed in the Administration Portal.

1.1.1 Adding VM Portal Permissions to a User

Users must be created already before they can be added and assigned roles and permissions. For more information, refer to Section 1.2, “Administering User and Group Accounts from the Command Line”.

In the following example procedure, a user is assigned the roles and permissions associated with the UserRole. This role gives the user the permission to log in to the VM Portal and to start creating virtual machines. The procedure also applies to group accounts.

1. Click Administration and then select Configure.

   The Configure dialog box opens with the Roles tab selected on the sidebar menu.

2. Click the System Permissions tab on the sidebar.

3. Click Add.

   The Add System Permission to User dialog box opens.

4. Select a profile from the Search drop-down list and click Go.
Removing Users and Groups

5. Select the check box next to the user or group account.
6. Under the Role to Assign drop-down list, select UserRole.
7. Click OK.
8. (Optional) Log in to the VM Portal to verify the permissions of the user account.

1.1.2 Removing Users and Groups

To use the Administration Portal to remove a user or group:

1. Go to Administration and then click Users.
   The Users pane opens.
2. On the Users pane, select either the User or Group tab to display the added users or groups.
3. Select the user or group to be removed.
4. Click Remove.
   The Remove User(s) dialog box opens.
5. Click OK to confirm the removal of the user.
   The user or group is removed and no longer appears on the Users pane.

1.1.3 Assigning Permissions to Users and Groups

Users and groups must be created already before they can be assigned roles and permissions. For more information, refer to Section 1.2, “Administering User and Group Accounts from the Command Line”.

1. Go to Administration and then click Users.
   The Users pane opens.
2. Click Add.
   The Add Users and Groups dialog box opens.
3. Select either the Users option.
4. In the Search field, enter the name of the user or group to be added and then select Go.
   The dialog box updates to display the search results.
5. Select the check box next to the user or group to be added.
6. Click Add.
   The user or group is added and appears on the Users pane.
7. On the Users pane, select either the User or Group tab to display the added users or groups.
8. Display the detailed view for the user or group by clicking the name of the user under the User Name column or the name of the group under the Group Name column.
9. Click the Permissions tab.
Creating a Custom Role

10. Click Add System Permissions.

   The Add System Permission to User dialog box opens.

11. From the Add System Permission to User drop-down list, select the role to assign to the user.

### 1.1.4 Creating a Custom Role

If you require a role that is not available in the default set of roles provided by the Manager, you can create a custom role.

![Note]

For more information about the default set of roles provided by the Manager, refer to [oVirt Documentation](#).

To create a custom role:

1. Click Administration and then select Configure.

   The Configure dialog box opens with the Roles tab selected on the sidebar menu. The Roles tab displays a list of administrator and user roles, and any custom roles that have been created.

2. Click New.

   The New Role dialog box opens.

3. For the Name and Description fields, enter an appropriate name and description for the role.

4. Under Account Type, select either Admin or User.

5. Under Check Boxes to Allow Action, select the appropriate objects whose permissions to assign to the user.

   Click Expand All to see the objects under each permissions group. Click Collapse All to collapse the list of objects under each of the permission group.

6. For each of the objects, select or clear the objects the actions to be permitted or denied for the custom role that is being created.

7. Click OK to create the custom role.

The custom role now appears on the Roles tab.

### 1.2 Administering User and Group Accounts from the Command Line

The following sections describe the common tasks that can be performed to administer user accounts using the ovirt-aaa-jdbc-tool command utility. This utility is used to manage user and group accounts on the internal domain. To view a list all available options for managing user and group accounts, run the ovirt-aaa-jdbc-tool --help command.

![Note]

Changes made using ovirt-aaa-jdbc-tool command utility take effect immediately and do not require you to restart the Manager.
1.2.1 Creating a New User Account

The `ovirt-aaa-jdbc-tool user add` command is used to create user accounts.

To create a new user account:

1. Log in to the host that is running the Manager.
2. Create a new user account.

   ```
   ovirt-aaa-jdbc-tool user add username option
   ```

To view a full list of options available for creating a user account, run the `ovirt-aaa-jdbc-tool user add --help` command.

The following example shows how to create a new user account and add a first and last name to associate with the account.

```bash
# ovirt-aaa-jdbc-tool user add test1 --attribute=firstName=John --attribute=lastName=Doe
adding user test1...
user added successfully
```

Note: by default created user cannot log in. see: /usr/bin/ovirt-aaa-jdbc-tool user password-reset --help.

3. Add the newly created user in the Administration Portal and assign the group appropriate roles and permissions. See Section 1.1.3, “Assigning Permissions to Users and Groups”.

1.2.2 Setting the Password for a User Account

The `ovirt-aaa-jdbc-tool password-reset` command is used to set (or reset) passwords for a user account.

To set (or reset) the password for a user account:

1. Log in to the host that is running the Manager.
2. Set (or reset) the password for a user account.

   ```
   ovirt-aaa-jdbc-tool user password-reset username --password-valid-to yyyy-MM-dd HH:mm:ssX
   ```

Note

You must set a value for the `--password-valid-to` option; otherwise the password expiry time defaults to the time of the last login.

By default, the password policy for user accounts on the internal domain has the following restrictions:

- A user password must be a minimum length of 6 characters.
- When resetting a password, you cannot use the three previous passwords used for the user account.

For more information on the password policy and other default settings, run the `ovirt-aaa-jdbc-tool settings show` command.
The following example shows how to set a user password. In the example, \texttt{0800} stands for GMT minus 8 hours.

\begin{verbatim}
# ovirt-aaa-jdbc-tool user password-reset test1 --password-valid-to="2025-08-01 12:00:00-0800"
Password:
Reenter password:
updating user test1...
user updated successfully
\end{verbatim}

### 1.2.3 Editing User Information

The \texttt{ovirt-aaa-jdbc-tool user edit} command is used to edit user information associated with a user account.

To edit user information:

1. Log in to the host that is running the Manager.
2. Edit the user account.

\begin{verbatim}
ovirt-aaa-jdbc-tool user edit username option
\end{verbatim}

To view a full list of options available for editing user information, run the \texttt{ovirt-aaa-jdbc-tool user edit --help} command.

The following example shows to edit a user account by adding an email address to associate with this user.

\begin{verbatim}
# ovirt-aaa-jdbc-tool user edit test1 --attribute=email=jdoe@example.com
updating user test1...
user updated successfully
\end{verbatim}

### 1.2.4 Viewing User Information

The \texttt{ovirt-aaa-jdbc-tool user show} command is used to display user information.

To view detailed user information:

1. Log in to the host that is running the Manager.
2. Display information about a user.

\begin{verbatim}
ovirt-aaa-jdbc-tool user show username
\end{verbatim}

The following example shows how to view details about a user account.

\begin{verbatim}
# ovirt-aaa-jdbc-tool user show test1
-- User test1(e9e4b7d0-8ffd-45a3-b6ea-1f519238e766) --
Namespace: *
Name: test1
ID: e9e4b7d0-8ffd-45a3-b6ea-1f519238e766
Display Name: 
Email: jdoe@example.com
First Name: John
Last Name: Doe
Department: 
Title: 
Description: 
Account Disabled: false
Account Locked: false
Account Unlocked At: 1970-01-01 00:00:00Z
\end{verbatim}
1.2.5 Removing a User

The `ovirt-aaa-jdbc-tool user delete` command is used to remove a user.

To remove a user account:

1. Log in to the host that is running the Manager.
2. Remove a user.

```
ovirt-aaa-jdbc-tool user delete username
```

The following example shows how to remove a user account.

```
# ovirt-aaa-jdbc-tool user delete test1
deleting user test1...
user deleted successfully
```

1.2.6 Disabling User Accounts

You can disable users on the local domains, including the internal `admin` user created when you run the `engine-setup` command.

**Important**

Make sure you have at least one user in the environment with full administrative permissions before disabling the default internal administrative user account (`admin` user). The `SuperUser` role gives a user full administrative permissions.

To disable a user:

1. Log in to the host that is running the Manager.
2. Disable the user.

```
ovirt-aaa-jdbc-tool user edit username --flag=+disabled
```

The following example shows how to disable the `admin` user.

```
# ovirt-aaa-jdbc-tool user edit admin --flag=+disabled
updating user admin...
user updated successfully
```

**Note**

If for some reason you need to re-enable the internal `admin` user after it has been disabled, you can do so by running the `ovirt-aaa-jdbc-tool user edit admin --flag=-disabled` command.

1.2.7 Creating Group Accounts

The `ovirt-aaa-jdbc-tool` command is used to create and manage group accounts on the internal domain. Managing group accounts is similar to managing user accounts. To view all available options
for managing group accounts, run the `ovirt-aaa-jdbc-tool group --help` command. Common examples are provided in this section.

### Creating a Group

To create a group account:

1. Log in to the host that is running the Manager.

2. Create a new group account.

   ```
   ovirt-aaa-jdbc-tool group add group-name
   ```

   **Note**

   Users must be created before they can be added to groups.

   The following examples shows how to add a new group account.

   ```
   # ovirt-aaa-jdbc-tool group add group1
   adding group group1...
   group added successfully
   ```

3. Add users to the group:

   ```
   ovirt-aaa-jdbc-tool group-manage useradd group-name --user= username
   ```

   To view a full list of the options for adding or removing members to and from groups, run the `ovirt-aaa-jdbc-tool group-manage --help` command.

   The following example shows how to add users to a group.

   ```
   # ovirt-aaa-jdbc-tool group-manage useradd group1 --user test1
   updating user group1...
   user updated successfully
   ```

4. Display group account details.

   ```
   ovirt-aaa-jdbc-tool group show group-name
   ```

   The following example shows how to display details about a group account.

   ```
   # ovirt-aaa-jdbc-tool group show group1
   -- Group group1(f23ca27c-1d6a-4f6e-8c3e-1e03e8e56829) --
   Namespace: *
   Name: group1
   ID: f23ca27c-1d6a-4f6e-8c3e-1e03e8e56829
   Display Name: 
   Description: 
   ```

5. Add the newly created group in the Administration Portal and assign the group appropriate roles and permissions. See Section 1.1.3, “Assigning Permissions to Users and Groups”.

   The users in the group inherit the roles and permissions of the group.

### Creating Nested Groups

To create nested groups:

1. Log in to the host that is running the Manager.
Removing a Group Account

2. Create the first group account.

```bash
ovirt-aaa-jdbc-tool group add group1
```

The following examples shows how to add a new group account.

```bash
# ovirt-aaa-jdbc-tool group add group1
adding group group1...
group added successfully
```

3. Create the second group account.

```bash
ovirt-aaa-jdbc-tool group add group2
```

The following examples shows how to create the second group account.

```bash
# ovirt-aaa-jdbc-tool group add group2
adding group group2...
group added successfully
```

4. Add the second group to the first group.

```bash
ovirt-aaa-jdbc-tool group manage group add group1 --group=group2
```

The following examples shows how to add the second group to the first group.

```bash
# ovirt-aaa-jdbc-tool group manage group add group1 --group=group2
updating group group1...
group updated successfully
```

5. Add the first group in the Administration Portal and assign the group appropriate roles and permissions. See Section 1.1.3, “Assigning Permissions to Users and Groups”.

1.2.8 Removing a Group Account

To remove a group account:

1. Log in to the host that is running the Manager.

2. Remove a group account.

```bash
ovirt-aaa-jdbc-tool group delete group-name
```

The following example shows how to remove a group account.

```bash
# ovirt-aaa-jdbc-tool group delete group3
deleting group group3...
group deleted successfully
```

1.2.9 Querying Users and Groups

The `ovirt-aaa-jdbc-tool query` command is used to query user and group information. To view a full list of options available for querying users and groups, run the `ovirt-aaa-jdbc-tool query --help` command.

**Listing All User or Group Account Details**

To list all account information:
Querying Users and Groups

1. Log in to the host that is running the Manager.
2. Display account details.
   - List all user account details.

   `ovirt-aaa-jdbc-tool query --what=user`

   The following example shows sample output from the `ovirt-aaa-jdbc-tool query --what=user` command.

   ```
   # ovirt-aaa-jdbc-tool query --what=user
   -- User test2(35e8b35e-2320-45da-b59e-1076b521d13f) --
   Namespace: *
   Name: test2

<tr>
<td>Last unsuccessful Login At: 1970-01-01 00:00:00Z</td>
</tr>
</tbody>
</table>

- List all group account details.

```bash
ovirt-aaa-jdbc-tool query --what=group
```

The following example shows sample output from the `ovirt-aaa-jdbc-tool query --what=group` command.

```
# ovirt-aaa-jdbc-tool query --what=group
-- Group group2(d6e0b913-d038-413a-b732-bc0c33ea1ed4) --
Namespace: *
Name: group2
ID: d6e0b913-d038-413a-b732-bc0c33ea1ed4
Display Name:
Description:

Listing Filtered Account Details

To apply filters when listing account information:

1. Log in to the host that is running the Manager.
2. Filter account details using the `--pattern` keyword.

- List user account based on a pattern.

```bash
ovirt-aaa-jdbc-tool query --what=user --pattern=
```

The following example shows how to filter the output of the `ovirt-aaa-jdbc-tool query` command to display only user account details that start with the character `J`.

```
# ovirt-aaa-jdbc-tool query --what=user --pattern="firstName=J*"
-- User test1(e75956a8-6ebf-49d7-94fa-504afbf96ad) --
Namespace: *

Account Locked: false
Account Unlocked At: 1970-01-01 00:00:00Z
```
1.2.10 Managing Account Settings

The `ovirt-aaa-jdbc-tool` command is used to change the default account settings.

To change the default account settings:

1. Log in to the host that is running the Manager.

2. (Optional) Display all the settings that are available.

   `ovirt-aaa-jdbc-tool setting show`

3. Change the desired settings.

   `ovirt-aaa-jdbc-tool setting set --name=setting-name --value=value`

- List groups based on a pattern.

  `ovirt-aaa-jdbc-tool-query --what=group --pattern=attribute=value`

  The following example shows how to filter the output of the `ovirt-aaa-jdbc-tool query` command to display only group account details that match the description `documentation-group`.

  ```
  # ovirt-aaa-jdbc-tool-query --what=group --pattern="description=documentation-group"
  -- Group group1(f23ca27c-1d6a-4f6e-8c3e-1e03e8e56829) --
  Namespace: *
  Name: group1
  ID: f23ca27c-1d6a-4f6e-8c3e-1e03e8e56829
  Display Name:
  Description: documentation-group
  ```

The following are common Oracle Linux Virtualization Manager administration tasks. For conceptual information about these topics, refer to the Oracle Linux Virtualization Manager: Architecture and Planning Guide.

For additional administrative tasks, see the oVirt Documentation.

2.1 Data Centers

Oracle Linux Virtualization Manager creates a default data center during installation. You can configure the default data center, or set up new appropriately named data centers.

A data center requires a functioning cluster, host, and storage domain to operate in your virtualization environment.

2.1.1 Creating a New Data Center

To create a new data center:
Clusters

1. Go to Compute and then select Data Centers.
   The Data Centers pane opens.
2. Click New.
3. Enter a Name and optional Description.
4. Select the storage Type, Compatibility Version, and Quota Mode of the data center from the respective drop-down menus.
5. Click OK to create the data center.
   The new data center is added to the virtualization environment and the Data Center - Guide Me menu opens to guide you through the entities that are required be configured for the data center to operate.
   The new data center remains in Uninitialized state until a cluster, host, and storage domain are configured for it.
   You can postpone the configuration of these entities by clicking the Configure Later button. You can resume the configuration of these entities by selecting the respective data center and clicking More Actions and then choosing Guide Me from the drop-down menu.

2.2 Clusters

Oracle Linux Virtualization Manager creates a default cluster in the default data center during installation. You can configure the default cluster, or set up new appropriately named clusters.

2.2.1 Creating a New Cluster

To create a new cluster:
1. Go to Compute and then select Clusters.
   The Clusters pane opens.
2. Click New.
   The New Cluster dialog box opens with the General tab selected on the sidebar.
3. From the Data Center drop-down list, choose the Data Center to associate with the cluster.
4. For the Name field, enter an appropriate name for the data center.
5. For the Description field, enter an appropriate description for the cluster.
6. From the Management Network drop-down list, choose the network for which to assign the management network role.
7. From the CPU Architecture and CPU Type drop-down lists, choose the CPU processor family and minimum CPU processor that match the hosts that are to be added to the cluster.
   For both Intel and AMD CPU types, the listed CPU models are in logical order from the oldest to the newest. If your cluster includes hosts with different CPU models, choose the oldest CPU model from the list to ensure that all hosts can operate in the cluster.
8. From the Compatibility Version drop-down list, choose the compatibility version of the cluster.
9. From the **Switch Type** drop-down list, choose the type of switch to be used for the cluster.

   By default, **Linux Bridge** is selected from the drop-down list.

10. From the **Firewall Type** drop-down list, choose the firewall type for hosts in the cluster.

    The firewall types available are either **iptables** or **firewalld**. By default, the **firewalld** option is selected from the drop-down list.

11. The **Enable Virt Service** check box is selected by default. This check box designates that the cluster is to be populated with virtual machine hosts.

12. *(Optional)* Review the other tabs to further configure your cluster:

   a. Click the **Optimization** tab on the sidebar to select the memory page sharing threshold for the cluster, and optionally enable CPU thread handling and memory ballooning on the hosts in the cluster. See Chapter 3, *Deployment Optimization*.

   b. Click the **Migration Policy** tab on the sidebar menu to define the virtual machine migration policy for the cluster.

   c. Click the **Scheduling Policy** tab on the sidebar to optionally configure a scheduling policy, configure scheduler optimization settings, enable trusted service for hosts in the cluster, enable HA Reservation, and add a custom serial number policy.

   d. Click the **Fencing policy** tab on the sidebar to enable or disable fencing in the cluster, and select fencing options.

   e. Click the **MAC Address Pool** tab on the sidebar to specify a MAC address pool other than the default pool for the cluster.

13. Click **OK** to create the data center.

   The cluster is added to the virtualization environment and the **Cluster - Guide Me** menu opens to guide you through the entities that are required to be configured for the cluster to operate.

   You can postpone the configuration of these entities by clicking the **Configure Later** button. You can resume the configuration of these entities by selecting the respective cluster and clicking **More Actions** and then choosing **Guide Me** from the drop-down menu.

### 2.3 Networks

With Oracle Linux Virtualization Manager, you can create custom vNICs for your virtual machines.

#### 2.3.1 Customizing vNIC Profiles for Virtual Machines

To customize vNICs for virtual machines:

1. Go to **Compute** and then click **Virtual Machines**.
Attaching and Configuring a Logical Network to a Host Network Interface

The Virtual Machines pane opens with the list of virtual machines that have been created.

2. Under the Name column, select the virtual machine for which to add the virtual machine network.

   The General tab opens with details about the virtual machine.

3. Click the Network Interfaces tab.

   The Network Interfaces tab opens with the available network interface to be used for the network.

4. Highlight the network interface by clicking the row for the respective interface and then click Edit on the right side above the interface listing.

   The Edit Network Interface dialog box opens.

5. In the Edit Network Interface dialog box, update the following fields:

   a. From the Profile drop-down list, select the network to be added to the virtual machine.

   b. Click the Custom MAC address check box, and then enter or update the MAC address that is allocated for this virtual machine in the text entry field.

6. Click OK when you are finished editing the network interface settings for the virtual machine.

7. Go to Compute and then click Virtual Machines.

   The Virtual Machines pane opens.

   Important

   Since virtual machines can start on any host in a data center/cluster, all hosts must have the customized VM network assigned to one of its NICs. Ensure that you assign this customized VM network to each host before booting the virtual machine. For more information, see Assigning a Virtual Machine Network to a KVM Host in the Oracle Linux Virtualization Manager: Getting Started Guide.

8. Highlight the virtual machine where you added the network and then click Run to boot the virtual machine.

   The red down arrow icon to the left of the virtual machine turns green and the Status column displays UP when the virtual machine is up and running on the network.

2.3.2 Attaching and Configuring a Logical Network to a Host Network Interface

You can change the settings of physical host network interfaces, move the management network from one physical host network interface to another, and assign logical networks to physical host network interfaces.

Before you begin the steps below, keep in mind the following:

• To change the IP address of a host, you must remove the host and then re-add it.

• To change the VLAN settings of a host, see Editing a Host’s VLAN Settings in oVirt Documentation.

• You cannot assign logical networks offered by external providers to physical host network interfaces; such networks are dynamically assigned to hosts as they are required by virtual machines.

• If a switch has been configured to provide Link Layer Discovery Protocol (LLDP) information, you can hover your cursor over a physical network interface to view the switch port’s current configuration.
Attaching and Configuring a Logical Network to a Host Network Interface

**Note**

Before assigning logical networks, check the configuration. To help detect to which ports and on which switch the host's interfaces are patched, review **Port Description (TLV type 4)** and **System Name (TLV type 5)**. The **Port VLAN ID** shows the native VLAN ID configured on the switch port for untagged ethernet frames. All VLANs configured on the switch port are shown as **VLAN Name** and **VLAN ID** combinations.

To edit host network interfaces and assign logical networks:

1. Click **Compute Hosts**.
2. Click the host's name. This opens the details view.
3. Click the **Network Interfaces** tab.
4. Click **Setup Host Networks**.
5. Optionally, hover your cursor over host network interface to view configuration information provided by the switch.
6. Attach a logical network to a physical host network interface by selecting and dragging the logical network into the **Assigned Logical Networks** area next to the physical host network interface.
   
   If a NIC is connected to more than one logical network, only one of the networks can be non-VLAN. All the other logical networks must be unique VLANs.
7. Configure the logical network.
   a. Hover your cursor over an assigned logical network and click the pencil icon. This opens the **Edit Management Network** window.
   b. Configure IPv4 or IPv6:
      
      - From the **IPv4** tab, set the **Boot Protocol**. If you select **Static**, enter the **IP**, **Netmask / Routing Prefix**, and the **Gateway**.
      
      - From the **IPv6** tab:
        
        - Set the **Boot Protocol** to **Static**.
        
        - For Routing Prefix, enter the length of the prefix using a forward slash and decimals. For example: /48 IP:
        
        - In the IP field, enter the complete IPv6 address of the host network interface. For example: 2001:db8::1:0:0:6
        
        - In the Gateway field, enter the source router’s IPv6 address. For example: 2001:db8::1:0:0:1

   **Note**

   If you change the host’s management network IP address, you must reinstall the host for the new IP address to be configured.

   Each logical network can have a separate gateway defined from the management network gateway. This ensures traffic that arrives on the
logical network is forwarded using the logical network’s gateway instead of
the default gateway used by the management network.

Set all hosts in a cluster to use the same IP stack for their management
network; either IPv4 or IPv6 only.

c. To configure a network bridge, click the Custom Properties tab, select bridge_opts from the list, and enter a valid key and value with the syntax of key=value.

The following are valid keys with example values:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>forward_delay</td>
<td>1500</td>
</tr>
<tr>
<td>group_addr</td>
<td>1:80:c2:0:0:0</td>
</tr>
<tr>
<td>group_fwd_mask</td>
<td>0x0</td>
</tr>
<tr>
<td>hash_max</td>
<td>512</td>
</tr>
<tr>
<td>hello_time</td>
<td>200</td>
</tr>
<tr>
<td>max_age</td>
<td>2000</td>
</tr>
<tr>
<td>multicast_last_member_count</td>
<td>2</td>
</tr>
<tr>
<td>multicast_last_member_interval</td>
<td>100</td>
</tr>
<tr>
<td>multicast_membership_interval</td>
<td>26000</td>
</tr>
<tr>
<td>multicast_querier</td>
<td>0</td>
</tr>
<tr>
<td>multicast_querier_interval</td>
<td>25500</td>
</tr>
<tr>
<td>multicast_query_interval</td>
<td>13000</td>
</tr>
<tr>
<td>multicast_query_response_interval</td>
<td>1000</td>
</tr>
<tr>
<td>multicast_query_use_ifaddr</td>
<td>0</td>
</tr>
<tr>
<td>multicast_router</td>
<td>1</td>
</tr>
<tr>
<td>multicast_snooping</td>
<td>1</td>
</tr>
<tr>
<td>multicast_startup_query_count</td>
<td>2</td>
</tr>
<tr>
<td>multicast_startup_query_interval</td>
<td>3125</td>
</tr>
</tbody>
</table>

Separate multiple entries with a whitespace character.

d. To configure ethernet properties, click the Custom Properties tab, select ethtool_opts from the list, and enter a valid value using the format of the command-line arguments of ethtool. For example:

```
--coalesce em1 rx-usecs 14 sample-interval 3 --offload em2 rx on lro on tso off \
--change em1 speed 1000 duplex half
```

You can use wildcard to apply the same option to all of a network’s interfaces, for example:

```
--coalesce * rx-usecs 14 sample-interval 3
```

The ethtool_opts option is not available by default; you need to add it using the engine configuration tool. To view ethtool properties, from a command line type man ethtool to open the man page. For more information, see How to Set Up oVirt Engine to Use Ethtool in oVirt Documentation.

e. To configure Fibre Channel over Ethernet (FCoE), click the Custom Properties tab, select fcoe from the list, and enter enable=yes. Separate multiple entries with a whitespace character.

The fcoe option is not available by default; you need to add it using the engine configuration tool. For more information, see How to Set Up oVirt Engine to Use FCoE in oVirt Documentation.

f. To change the default network used by the host from the management network (ovirtmgmt) to a non-management network, configure the non-management network’s default route. For more information, see Configuring a Non-Management Logical Network as the Default Route in oVirt Documentation.
g. If your logical network definition is not synchronized with the network configuration on the host, select the **Sync network** check box. For more information about unsynchronized hosts and how to synchronize them, see *Synchronizing Host Networks* in *oVirt Documentation*.

8. To check network connectivity, select the **Verify connectivity between Host and Engine** check box.

   ![Note](image)
   
   The host must be in maintenance mode.

9. Click **OK**.

   ![Note](image)
   
   If not all network interface cards for the host are displayed, click **Management** and then **Refresh Capabilities** to update the list of network interface cards available for that host.

### 2.4 Storage

Oracle Linux Virtualization Manager uses a centralized storage system for virtual machine disk images, ISO files, and snapshots. You can use Network File System (NFS), Internet Small Computer System Interface (iSCSI), or Fibre Channel Protocol (FCP) storage. You can also configure local storage attached directly to hosts.

This following administration tasks cover preparing and adding local, NFS, and FCP storage. For information about attaching iSCSI storage, see *Attaching an iSCSI Data Domain* in the *Oracle Linux Virtualization Manager: Getting Started Guide*.

#### 2.4.1 Preparing Local Storage for a KVM Host

Before you begin, ensure the following prerequisites have been met:

- You have allocated disk space for local storage. You can allocate an entire physical disk on the host or you can use a portion of the disk.

- You have created a filesystem on the block device path to be used for local storage. Local storage should always be defined on a file system that is separate from the root directory (`/root`).

To prepare local storage for a KVM host:

1. Create the directory to be used for the local storage on the host.

   ```bash
   # mkdir -p /data/images
   ```

2. Ensure that the directory has permissions that allows read-write access to the `vdsm` user (UID 36) and `kvm` group (GID 36).

   ```bash
   # chown 36:36 /data /data/images
   # chmod 0755 /data /data/images
   ```

   The local storage can now be added to your virtualization environment.
2.4.2 Configuring a KVM Host to Use Local Storage

When you configure a KVM host to use local storage, it is automatically added to a new data center and cluster that can contain no other hosts. With local storage, features, such as live migration, fencing, and scheduling, are not available.

To configure a KVM host to use local storage:

1. Go to Compute, and then click Hosts.
   The Hosts pane opens.

2. Highlight the host on which to add the local storage domain.

3. Click Management and then select Maintenance from the drop-down list.
   The Status column for the host displays Maintenance when the host has successfully entered into Maintenance mode.

4. After the host is in Maintenance mode, click Management and then select Configure Local Storage from the drop-down list.
   The Configure Local Storage pane opens with the General tab selected.

5. Click Edit next to the Data Center, Cluster, and Storage fields to configure and name the local storage domain.

6. In the Set the path to your local storage text input field, specify the path to your local storage domain.
   For more information, refer to Section 2.4.1, “Preparing Local Storage for a KVM Host”.

7. Click OK to add the local storage domain.

When the virtualization environment is finished adding the local storage, the new data center, cluster, and storage created for the local storage appears on the Data Center, Clusters, and Storage panes, respectively.

You can click Tasks to monitor the various processing steps that are completed to add the local storage to the host.

You can also verify the successful addition of the local storage domain by viewing the /var/log/ovirt-engine/engine.log file.

2.4.3 Preparing NFS Storage

Before preparing the NFS share, ensure your environment meets the following conditions:

- Ensure that the Manager and KVM host installation are running the latest Oracle Linux 7.6 (or later) in an environment with two or more servers where one acts as the Manager host and the other servers act as KVM hosts.

The installation creates a vdsm:kvm (36:36) user and group in the /etc/passwd and /etc/group directories, respectively.

```
# cat /etc/passwd | grep vdsm
vdsm:x:36:36:Node Virtualization Manager::/sbin/nologin

# cat /etc/group | grep kvm
kvm:x:36:qemu,sanlock
```
• An Oracle Linux NFS File server that is reachable by your virtualization environment.

To prepare NFS storage:

1. On a Linux fileserver that has access to the virtualization environment, create a directory that is to be used for the data domain.

   ```
   mkdir -p /nfs/olv_ovirt/data
   ```

2. Set the required permissions on the new directory to allow read-write access to the `vdsm` user (UID 36) and `kvm` group (GID 36).

   ```
   chown -R 36:36 /nfs/olv_ovirt
   chmod -R 0755 /nfs/olv_ovirt
   ```

3. Add an entry for the newly created NFS share in the `/etc/exports` directory on the NFS file server that uses the following format: `full-path-of-share-created *(rw,sync,no_subtree_check,all_squash,anonuid=36,anongid=36)`.

   For example:

   ```
   vi /etc/exports
   # added the following entry
   /nfs/olv_ovirt/data *(rw,sync,no_subtree_check,all_squash,anonuid=36,anongid=36)
   :wq
   ```

   Verify that the entry has been added.

   ```
   grep "/nfs/olv_ovirt/data" /etc/exports
   /nfs/olv_ovirt/data *(rw,sync,no_subtree_check,all_squash,anonuid=36,anongid=36)
   ```

   If you do not want to export the domain share to all servers on the network (denoted by the `*` before the left parenthesis), you can specify each individual host in your virtualization environment by using the following format: `/nfs/ol_ovirt/data hostname-or-ip-address (rw,sync,no_subtree_check,all_squash,anonuid=36,anongid=36)`.

   For example:

   ```
   /nfs/olv_ovirt/data hostname (rw,sync,no_subtree_check,all_squash,anonuid=36,anongid=36)
   ```

4. Export the NFS share.

   ```
   exportfs -rv
   ```

5. Confirm that the added export is available to Oracle Linux Virtualization Manager hosts by using the following `showmount` commands on the NFS File Server.

   ```
   showmount -e | grep pathname-to-domain-share-added
   showmount | grep ip-address-of-host
   ```

### 2.4.4 Attaching an NFS Data Domain

To attach an NFS data domain:

1. Go to Storage and then click Domains.

   The Storage Domains pane opens.

2. Click New Domain.
Adding an FC Data Domain

The New Domain dialog box opens.

3. From the Data Center drop-down list, select the Data Center for which to attach the data domain.

4. From the Domain Function drop-down list, select Data. By default, the Data option is selected in the drop-down list.

5. From the Storage Type drop-down list, select NFS. By default, the NFS option is selected in the drop-down list.

When NFS is selected for the Storage Type, the options that are applicable to this storage types (such as the required Export Path option) are displayed in the New Domain dialog box.

6. For the Host to Use drop-down list, select the host for which to attach the data domain.

7. For the Export Path option, enter the remote path to the NFS export to be used as the storage data domain in the text input field.

The Export Path option must be entered in one of the following formats: IP:/pathname or FQDN:/pathname (for example, server.example.com:/nfs/olv_ovirt/data).

The /pathname that you enter must be the same as the path that you created on the NFS file server for the data domain in Section 2.4.3, “Preparing NFS Storage”.

8. Click OK to attach the NFS storage data domain.

For information about uploading images to the data domain, see Uploading Images to a Data Domain in the Oracle Linux Virtualization Manager: Getting Started Guide.

2.4.5 Adding an FC Data Domain

To add an FC data domain:

1. Go to Storage and then click Domains.

The Storage Domains pane opens.

2. On the Storage Domains pane, click the New Domain button.

The New Domain dialog box opens.

3. For the Name field, enter a name for the data domain.

4. From the Data Center drop-down list, select the Data Center for which to attach the data domain. By default, the Default option is selected in the drop-down list.

5. From the Domain Function drop-down list, select the domain function. By default, the Data option is selected in the drop-down list.

For this step, leave Data as the domain function because you are creating a data domain in this example.

6. From the Storage Type drop-down list, select Fibre Channel.

7. For the Host to Use drop-down list, select the host for which to attach the data domain.

8. When Fibre Channel is selected for the Storage Type, the New Domain dialog box automatically displays the known targets with unused LUNs.
9. Click **Add** next to the LUN ID that is connect to the target.

10. **(Optional)** Configure the advanced parameters.

11. Click **OK**.

   You can click **Tasks** to monitor the various processing steps that are completed to attach the FC data domain to the data center.

### 2.4.6 Detaching a Storage Domain from a Data Center

A storage domain must be in maintenance mode before it can be detached and removed. This is required to redesignate another data domain as the master data domain.

You cannot move a storage domain into maintenance mode if a virtual machine has a lease on the storage domain. The virtual machine needs to be shut down, or the lease needs to be to removed or moved to a different storage domain first.

To detach a storage domain from one data center to migrate it to another data center:

1. Shut down all the virtual machines running on the storage domain.

2. Go to **Storage** and then click **Domains**.

   The **Storage Domains** pane opens.

3. Click the storage domain’s name.

   The details view of the storage domain opens.

4. Click the **Data Center** tab.

5. Click **Maintenance**.

   The **Ignore OVF update failure** check box allows the storage domain to go into maintenance mode even if the OVF update fails.

   **Note**

   The OVF_STORE disks are images that contain the metadata of virtual machines and disks that reside on the storage data domain.

6. Click **OK**.

   The storage domain is deactivated and has an **Inactive** status in the results list. You can now detach the inactive storage domain from the data center.

7. Click **Detach**.

8. Click **OK** to detach the storage domain.

   Now that the storage domain is detached from the data center, it can be attached to another data center.

### 2.4.7 Configuring iSCSI Multipathing

Multiple network paths between hosts and iSCSI storage prevent host downtime caused by network path failure. iSCSI multipathing enables you to create and manage groups of logical networks and iSCSI storage connections.
The Engine connects each host in a data center to each storage target using the NICs or VLANs that are assigned to the logical networks in the iSCSI bond.

You can create an iSCSI bond with multiple targets and logical networks for redundancy.

Before you can configure iSCSI multipathing, ensure you have the following:

- One or more iSCSI targets. For more information, see *Attaching an iSCSI Data Domain* in the *Oracle Linux Virtualization Manager: Getting Started Guide*.

- One or more logical networks that are:
  - Not defined as Required or VM Network. For more information, see Section 2.4.8, “Migrating a Logical Network to an iSCSI Bond”.
  - Assigned to a host interface.
  - Assigned a static IP address in the same VLAN and subnet as the other logical networks in the iSCSI bond.

  For more information, see *Creating a Logical Network* in the *Oracle Linux Virtualization Manager: Getting Started Guide*.

To configure iSCSI multipathing:

1. Click **Compute Data Centers**.
2. Click the data center name.
3. In the **iSCSI Multipathing** tab, click **Add**.
4. In the **Add iSCSI Bond** window, enter a **Name** and optionally add a **Description**.
5. Select a logical network from **Logical Networks** and a storage domain from **Storage Targets**. You must select all paths to the same target.
6. Click **OK**.

The hosts in the data center are connected to the iSCSI targets through the logical networks in the iSCSI bond.

2.4.8 Migrating a Logical Network to an iSCSI Bond

If you have a logical network that you created for iSCSI traffic and configured on top of an existing network bond, you can migrate the logical network to an iSCSI bond on the same subnet without disruption or downtime.

To migrate a logical network to an iSCSI bond:

1. Modify the current logical network so that it is not required.
   a. Click **Compute** and then click **Clusters**.
   b. Click the cluster name.
   c. In the **Logical Networks** tab of the cluster detail page, select the current logical network (*net-1*) and click **Manage Networks**.
   d. Clear the **Require** check box and click **OK**.
2. Create a new logical network that is not Required and not VM network.
   a. Click Add Network. This opens the New Logical Network window.
   b. In the General tab, enter the Name (net-2) and clear the VM network check box.
   c. In the Cluster tab, clear the Require check box and click OK.

3. Remove the current network bond and reassign the logical networks.
   a. Click Compute and then click Hosts.
   b. Click the host name.
   c. In the Network Interfaces tab of the host detail page, click Setup Host Networks.
   d. Drag net-1 to the right to unassign it.
   e. Drag the current bond to the right to remove it.
   f. Drag net-1 and net-2 to the left to assign them to physical interfaces.
   g. To edit the net-2 network, click its pencil icon.
   h. In the IPV4 tab of the Edit Network window, select Static.
   i. Enter the IP and Netmask/Routing Prefix of the subnet and click OK.

4. Create the iSCSI bond.
   a. Click Compute and then click Data Centers.
   b. Click the data center name.
   c. In the iSCSI Multipathing tab of the data center details page, click Add.
   d. In the Add iSCSI Bond window, enter a Name, select the networks net-1 and net-2 and click OK.

Your data center has an iSCSI bond containing the old and new logical networks.

2.5 Virtual Machines

Oracle Linux Virtualization Manager lets you perform basic administration of your virtual machines, including live editing, creating and using snapshots and live migration.

Note
For information on creating virtual machines, see the Oracle Linux Virtualization Manager: Getting Started Guide.

2.5.1 Live Editing a Virtual Machine

You can optionally change many settings for a virtual machine while it is running.

1. From the Administration Portal, click Compute and then select Virtual Machines.

The Virtual Machines pane opens with the list of virtual machines that have been created.
2. Under the **Name** column, select the virtual machine you want to make changes to and then click **Edit**.

3. On the bottom left of the **Edit Virtual Machine** window, click **Show Advanced Options**.

4. Change any of the following properties while the virtual machine is running without restarting the virtual machine.

Select the **General** tab, to modify:

- **Optimized for**

  You can select from three options:

  - **Desktop** - the virtual machine has a sound card, uses an image (thin allocation), and is stateless.
  
  - **Server** - the virtual machine does not have a sound card, uses a cloned disk image, and is not stateless. In contrast, virtual machines optimized to act as desktop machines.
  
  - **High Performance** - the virtual machine is pre-configured with a set of suggested and recommended configuration settings for reaching the best efficiency.

- **Name**

  A virtual machine’s name must be unique within the data center. It must not contain any spaces and must contain at least one character from A-Z or 0-9. The maximum length is 255 characters.

  The name can be re-used in different data centers within Oracle Linux Virtualization Manager.

- **Description** and **Comment**

- **Delete Protection**

  If you want to make it impossible to delete a virtual machine, check this box. If you later decide you want to delete the virtual machine, remove the check.

- **Network Interfaces**

  Add or remove network interfaces or change the network of an existing NIC.

Select the **System** tab, to modify:

- **Memory Size**

  Use to hot plug virtual memory. For more information, see Section 3.2.2, “Hot Plugging Virtual Memory”.

- **Virtual Sockets** (Under **Advance Parameters**)

  Use to hot plug CPUs to the virtual machine. Do not assign more sockets to a virtual machine than are present on its KVM host. For more information, see Section 3.2.1, “Hot Plugging vCPUs”.

Select the **Console** tab, to modify:

- **Disable strict user checking**

  By default, strict checking is enabled allowing only one user to connect to the console of a virtual machine until it has been rebooted. The exception is that a SuperUser can connect at any time and
replace a existing connection. When a SuperUser has connected, no normal user can connect again until the virtual machine is rebooted.

**Important**

Check this box with caution because you can expose the previous user's session to the new user.

Select the **High Availability** tab, to modify:

- **Highly Available**
  
  Check this box if you want the virtual machine to automatically live migrate to another host if its host crashes or becomes non-operational. Only virtual machines with high availability are restarted on another host. If the virtual machine's host is manually shut down, the virtual machine does not automatically live migrate to another host. For more information, see Section 3.1.3, “Configuring a Highly Available Virtual Machine”.

**Note**

You are not able to check this box if on the **Host** tab you have selected either **Allow manual migration only** or **Do not allow migration** for the Migration mode. For a virtual machine to be highly-available it must be possible for the engine to migrate the virtual machine to another host when needed.

- **Priority for Run/Migration Queue**
  
  Select the priority level (**Low**, **Medium** or **High**) for the virtual machine to live migrate or restart on another host.

Select the **Icon** tab, to upload a new icon.

5. Click **OK** when you are finished with all tabs to save your changes.

Changes to any other settings are applied when you shut down and restart your virtual machine. Until then, an orange icon displays to indicate pending changes.

### 2.5.2 Migrating Virtual Machines between Hosts

Virtual machines that share the same storage domain can live migrate between hosts that belong to the same cluster. Live migration allows you to move a running virtual machine between physical hosts with no interruption to service. The virtual machine stays powered on and user applications continue running while the virtual machine is relocated to a new physical host. In the background, the virtual machine's RAM is copied from the source host to the destination host. Storage and network connectivity are not changed.

You use live migration to seamlessly move virtual machines to support a number of common maintenance tasks. Ensure that your environment is correctly configured to support live migration well in advance of using it.

#### 2.5.2.1 Configuring Your Environment for Live Migration

To enable successful live migrations, you should ensure you correctly configure it. At a minimum, to successfully migrate running virtual machines:

- Source and destination hosts should be in the same cluster
- Source and destination hosts must have a status of **Up**.
Migrating Virtual Machines between Hosts

- Source and destination hosts must have access to the same virtual networks and VLANs
- Source and destination hosts must have access to the data storage domain where the virtual machines reside
- There must be enough CPU capacity on the destination host to support the virtual machine's requirements.
- There must be enough RAM on the destination host that is not in use to support the virtual machine's requirements

**Note**
Live migrations are performed using the management network. The number of concurrent migrations supported is limited by default. Even with these limits, concurrent migrations can potentially saturate the management network. To minimize the risk of network saturation, we recommend that you create separate logical networks for storage, display, and virtual machine data.

To configure virtual machines so they reduce network outage during migration:

- Ensure that the destination host has an available virtual function (VF)
- Set the **Passthrough** and **Migrateable** options in the passthrough vNIC’s profile
- Enable hotplugging for the virtual machine's network interface
- Ensure that the virtual machine has a backup VirtIO vNIC to maintain the virtual machine's network connection during migration
- Set the VirtIO vNIC’s **No Network Filter** option before configuring the bond
- Add both vNICs as subordinate under an active-backup bond on the virtual machine, with the passthrough vNIC as the primary interface

### 2.5.2.2 Automatic Virtual Machine Migration

The Engine automatically initiates live migration of virtual machines in two situations:

- When a host is moved into maintenance mode live migration is initiated for all virtual machines running on the host. The destination host for each virtual machine is assessed as the virtual machine is migrated, in order to spread the load across the cluster.
- To maintain load balancing or power saving levels in line with scheduling policy live migrations are initiated.

You can disable automatic, or even manual, live migration of specific virtual machines if required.

### 2.5.2.3 Setting Virtual Machine Migration Mode

Using the **Migration mode** setting for a virtual machine, you can allow automatic and manual migration, disable automatic migration, or disable automatic and manual migration. If a virtual machine is configured to run only on a specific host, you cannot migrate in manually.

To set a virtual machine's migration mode:

From the **Migration mode** drop-down list, select **Allow manual and automatic migration**, **Allow manual migration only** or **Do not allow migration**.
To set the migration mode of a virtual machine:

1. Click **Compute** and select **Virtual Machines**.
2. Select a virtual machine and click **Edit**.
3. Click the **Host** tab.
4. Use the **Start Running On** radio buttons to specify whether the virtual machine should run on any host in the cluster, a specific host, or a group of hosts.

   If the virtual machine has host devices attached to it, and you choose a different host, the host devices from the previous host are removed from the virtual machine.

   **Warning**

   Assigning a virtual machine to one specific host and disabling migration is mutually exclusive in Oracle Linux Virtualization Manager high availability (HA). Virtual machines that are assigned to one specific host can only be made highly available using third-party HA products. This restriction does not apply to virtual machines that are assigned to a group of hosts.

5. From the **Migration mode** drop-down list, select **Allow manual and automatic migration**, **Allow manual migration only** or **Do not allow migration**.
6. **(Optional)** Check **Use custom migration downtime** and specify a value in milliseconds.
7. Click **OK**.

### 2.5.2.4 Manually Migrate a Virtual Machine

To manually migrate a virtual machine:

1. Click **Compute** and select **Virtual Machines**.
2. Select a running virtual machine and click **Migrate**.
3. Choose either **Select Host Automatically** or **Select Destination Host** and select the destination host from the drop-down list.

   When you choose **Select Host Automatically**, the system determines the destination host according to the load balancing and power management rules set up in the scheduling policy.

4. Click **OK**.

   During migration, progress is shown in the **Status** field. When the virtual machine has been migrated, the **Host** field updates to show the virtual machine's new host.

### 2.5.3 Importing an Oracle Linux Template

The *Oracle Linux Virtualization Manager: Getting Started Guide* has instructions on creating an Oracle Linux template. However, Oracle provides pre-installed and pre-configured templates that allow you to deploy a fully configured software stack. Use of Oracle Linux templates eliminates the installation and configuration costs and reduces the ongoing maintenance costs.

To import an Oracle Linux template:
1. Download a the template OVA file from http://yum.oracle.com/oracle-linux-templates.html and copy to your KVM host.

2. Assign permissions to the file.

   ```sh
c# chown 36:36 /tmp/<myfile>.ova
```

3. Ensure that the `kvm` user has access to the OVA file's path, for example:

   ```sh
   # -rw-r--r-- 1 vdsm kvm 872344576 Jan 15 17:43 OLKVM_OL7U7_X86_64.ova
```

4. In the Administration Portal, click **Compute** and then select **Templates**.

5. Click **Import**.

6. From the *Import Template(s)* window, select the following options:
   - Data Center: `<datacenter>`
   - Source: **Virtual Appliance (OVA)**
   - Host: `<kvm_host_containing_ova>`
   - File Path: `<full_path_to_ova_file>`

7. Click **Load**.

8. From the *Virtual Machines on Source* list, select the virtual appliance's check box.

   **Note**
   You can select more than one virtual appliance to import.

9. Click the right arrow to move the appliance(s) to the **Virtual Machines to Import** list and then click **Next**.

10. Click the **Clone** field for the template you want to import and review its **General**, **Network Interfaces**, and **Disks** configuration.

11. Click **OK**.

   The import process can take several minutes. Once it completes, you can view the template(s) by clicking **Compute** and then **Templates**.

   To create a virtual machine from your imported template, see **Creating an Oracle Linux Virtual Machine from a Template** in the *Oracle Linux Virtualization Manager: Getting Started Guide*.

### 2.5.4 Creating a Snapshot of a Virtual Machine

A snapshot is a view of a virtual machine’s operating system and applications on any or all available disks at a given point in time. You can take a snapshot of a virtual machine before you make a change to it that may have unintended consequences. If needed, you can use the snapshot to return the virtual machine to its previous state.

**Note**
For best practices when using snapshots, see **Considerations When Using Snapshots** in the *Oracle Linux Virtualization Manager: Architecture and Planning Guide*.
To create a snapshot of a virtual machine:

1. Click **Compute** and then select **Virtual Machines**.

   The **Virtual Machines** pane opens with the list of virtual machines that have been created.

2. Under the **Name** column, select the virtual machine for which to take a snapshot.

   The **General** tab opens with details about the virtual machine.

3. Click the **Snapshots** tab.

4. Click **Create**.

5. **(Optional)** For the **Description** field, enter a description for the snapshot.

6. **(Optional)** Select the **Disks to include** checkboxes. By default, all disks are selected.

   **Important**

   Not selecting a disk results in the creation of a partial snapshot of the virtual machine without a disk. Although a saved partial snapshot does not have a disk, you can still preview a partial snapshot to view the configuration of the virtual machine.

7. **(Optional)** Select the **Save Memory** check box to include the virtual machine's memory in the snapshot. By default, this checkbox is selected.

8. Click **OK** to save the snapshot.

   The virtual machine’s operating system and applications on the selected disks are stored in a snapshot that can be previewed or restored.

   On the **Snapshots** pane, the **Lock** icon appears next to the snapshot as it is being created. Once complete, the icon changes to the **Snapshot** (camera) icon. You can then display details about the snapshot by selecting the **General**, **Disks**, **Network Interfaces**, and **Installed Applications** drop-down views.

### 2.5.5 Restoring a Virtual Machine from a Snapshot

A snapshot can be used to restore a virtual machine to a previous state.

**Note**

The virtual machine must be in a **Down** state before performing this task.

To restore a virtual machine from a snapshot:

1. Click **Compute** and then select **Virtual Machines**.

   The **Virtual Machines** pane opens with the list of virtual machines that have been created.

2. Under the **Name** column, select the virtual machine that you want to restore from a snapshot.

   The **General** tab opens with details about the virtual machine.

3. Click the **Snapshots** tab.
4. On the **Snapshots** pane, select the snapshot to be used to restore the virtual machine.

5. From the **Preview** drop-down list, select **Custom**.

   On the **Virtual Machines** pane, the status of the virtual machine briefly changes to **Image Locked** before returning to **Down**.

   On the **Snapshots** pane, the **Preview** (eye) icon appears next to the snapshot when the preview of the snapshot is completed.

6. Click **Run** to start the virtual machine.

   The virtual machine runs using the disk image of the snapshot. You can preview the snapshot and verify the state of the virtual machine.

7. Click **Shutdown** to stop the virtual machine.

8. From the **Snapshot** pane, perform one of the following steps:
   
   a. Click **Commit** to permanently restore the virtual machine to the condition of the snapshot. Any subsequent snapshots are erased.
   
   b. Alternatively, click **Undo** to deactivate the snapshot and return the virtual machine to its previous state.

### 2.5.6 Creating a Virtual Machine from a Snapshot

Before performing this task, you must create a snapshot of a virtual machine. For more information, refer to Section 2.5.4, “Creating a Snapshot of a Virtual Machine”.

To create a virtual machine from a snapshot:

1. Click **Compute** and then select **Virtual Machines**.

   The **Virtual Machines** pane opens with the list of virtual machines that have been created.

2. Under the **Name** column, select the virtual machine with the snapshot that you want to use as the basis from which to create another virtual machine.

   The **General** tab opens with details about the virtual machine.

3. Click the **Snapshots** tab.

4. On the **Snapshots** pane, select the snapshot from which to create the virtual machine.

5. Click **Clone**.

   The **Clone VM from Snapshot** dialog box opens.

6. For the **Name** field, enter a name for the virtual machine.

   **Note**

   The **Name** field is the only required field on this dialog box.

   After a short time, the cloned virtual machine appears on the **Virtual Machines** pane with a status of **Image Locked**. The virtual machine remains in this state until the Manager completes the creation of
Deleting a Snapshot

the virtual machine. When the virtual machine is ready to use, its status changes from Image Locked to Down on the Virtual Machines pane.

2.5.7 Deleting a Snapshot

You can delete a virtual machine snapshot and permanently remove it from your virtualization environment. This operation is supported on a running virtual machine and does not require the virtual machine to be in a Down state.

Important

• When you delete a snapshot from an image chain, there must be enough free space in the storage domain to temporarily accommodate both the original volume and the newly merged volume; otherwise, the snapshot deletion fails. This is due to the data from the two volumes being merged in the resized volume and the resized volume growing to accommodate the total size of the two merged images. In this scenario, you must export and reimport the volume to remove the snapshot.

• If the snapshot being deleted is contained in a base image, the volume subsequent to the volume containing the snapshot being deleted is extended to include the base volume.

• If the snapshot being deleted is contained in a QCOW2 (thin-provisioned), non-base image hosted on internal storage, the successor volume is extended to include the volume containing the snapshot being deleted.

To delete a snapshot:

1. Click Compute and then select Virtual Machines.
   
   The Virtual Machines pane opens with the list of virtual machines that have been created.

2. Under the Name column, select the virtual machine with the snapshot that you want to delete.
   
   The General tab opens with details about the virtual machine.

3. Click the Snapshots tab.

4. On the Snapshots pane, select the snapshot to delete.

5. Select the snapshot to delete.

6. Click Delete.

7. Click OK.

   On the Snapshots pane, a Lock icon appears next to the snapshot until the snapshot is deleted.

2.6 Encrypted Communication

You can configure your organization’s third-party CA certificate to identify the Oracle Linux Virtualization Manager to users connecting over HTTPS.

Using a third-party CA certificate for HTTPS connections does not affect the certificate that is used for authentication between the engine host and KVM hosts. They continue to use the self-signed certificate generated by the Manager.
2.6.1 Replacing the Oracle Linux Virtualization Manager Apache SSL Certificate

Before you begin you must obtain a third-party CA certificate, which is a digital certificate issued by a certificate authority (CA). The certificate is provided as a PEM file. The certificate chain must be complete up to the root certificate. The chain’s order is critical and must be from the last intermediate certificate to the root certificate.

Caution
Do not change the permissions and ownerships for the /etc/pki directory or any subdirectories. The permission for the /etc/pki and /etc/pki/ovirt-engine directories must remain as the default value of 755.

To replace the Oracle Linux Virtualization Manager Apache SSL Certificate:

1. Copy the new third-party CA certificate to the host-wide trust store and update the trust store.

   ```
   # cp third-party-ca-cert.pem /etc/pki/ca-trust/source/anchors/
   # update-ca-trust export
   ```

2. Remove the symbolic link to /etc/pki/ovirt-engine/apache-ca.pem.

   The Engine has been configured to use /etc/pki/ovirt-engine/apache-ca.pem, which is symbolically linked to /etc/pki/ovirt-engine/ca.pem.

   ```
   # rm /etc/pki/ovirt-engine/apache-ca.pem
   ```

3. Copy the CA certificate into the PKI directory for the Manager.

   ```
   # cp third-party-ca-cert.pem /etc/pki/ovirt-engine/apache-ca.pem
   ```

4. Back up the existing private key and certificate.

   ```
   # cp /etc/pki/ovirt-engine/keys/apache.key.nopass/etc/pki/ovirt-engine/keys/ 
   apache.key.nopass.bck
   # cp /etc/pki/ovirt-engine/certs/apache.cer/etc/pki/ovirt-engine/certs/apache.cer.bck
   ```

5. Copy the new Apache private key into the PKI directory for the Manager by entering the following command and respond to prompt.

   ```
   # cp apache.key /etc/pki/ovirt-engine/keys/apache.key.nopass
   cp: overwrite \u2018/etc/pki/ovirt-engine/keys/apache.key.nopass\u2019? y
   ```

6. Copy the new Apache certificate into the PKI directory for the Manager by entering the following command and respond to the prompt.

   ```
   # cp apache.cer /etc/pki/ovirt-engine/certs/apache.cer
   cp: overwrite \u2018/etc/pki/ovirt-engine/certs/apache.cer\u2019? y
   ```

7. Restart the Apache HTTP server (httpd) and the Manager.

   ```
   # systemctl restart httpd
   # systemctl restart ovirt-engine
   ```

8. Create a new trust store configuration file (or edit the existing one) at /etc/ovirt-engine/ engine.conf.d/99-custom-truststore.conf by adding the following parameters.

   ```
   ENGINE_HTTPS_PKI_TRUST_STORE="/etc/pki/java/cacerts"
   ENGINE_HTTPS_PKI_TRUST_STORE_PASSWORD=""
   ```

   # cp /etc/ovirt-engine/ovirt-websocket-proxy.conf.d/10-setup.conf/etc/ovirt-engine/ \
   ovirt-websocket-proxy.conf.d/10-setup.conf.bck

10. Edit the Websocket configuration file at /etc/ovirt-engine/ovirt-websocket-proxy.conf.d/10-setup.conf by adding the following parameters.

   SSL_CERTIFICATE=/etc/pki/ovirt-engine/certs/apache.cer
   SSL_KEY=/etc/pki/ovirt-engine/keys/apache.key.nopass

11. Restart the ovirt-provider-ovn service.

   # systemctl restart ovirt-provider-ovn

12. Restart the ovirt-engine service.

   # systemctl restart ovirt-engine

2.7 Event Notifications

The following section explains how to set up event notifications to monitor events in your virtualization environment. You can configure the Manager to send event notifications in email to alert designated users when certain events occur or enable Simple Network Management Protocol (SNMP) traps to monitor your virtualization environment.

2.7.1 Configuring Event Notification Services on the Engine

For event notifications to be sent properly to email recipients, you must configure the mail server on the Engine and enable ovirt-engine-notifier service. For more information about creating event notifications in the Administration portal, see Section 2.7.2, “Creating Event Notifications in the Administration Portal”.

To configure notification services on the Engine:

1. Log in to the host that is running the Manager.

2. Copy the ovirt-engine-notifier.conf to a new file named 90-email-notify.conf.

   # cp /usr/share/ovirt-engine/services/ovirt-engine-notifier/ovirt-engine-notifier.conf/ \
   etc/ovirt-engine/notifier/notifier.conf.d/90-email-notify.conf

3. Edit the 90-email-notify.conf file by deleting everything except the EMAIL Notifications section.

   # EMAIL Notifications#

   Note

   If you plan to also configure SNMP traps in your virtualization environment, you can also copy the values from the SNMP_TRAP Notifications section of the ovirt-notifier.conf file to a file named 20-snmp.conf. For more information, see Section 2.7.4, “Configuring the Engine to Send SNMP Traps”.

4. Enter the correct email variables. This file overrides the values in the original ovirt-engine-notifier.conf file.

   # EMAIL Notifications #
Creating Event Notifications in the Administration Portal

```bash
# The SMTP mail server address. Required.
MAIL_SERVER=myemailserver.mycompany.com

# The SMTP port (usually 25 for plain SMTP, 465 for SMTP with SSL, 587 for SMTP with TLS)
MAIL_PORT=25

# Required if SSL or TLS enabled to authenticate the user. Used also to specify 'from'
# user address if mail server
# supports, when MAIL_FROM is not set. Address is in RFC822 format
MAIL_USER=email.example.com

# Required to authenticate the user if mail server requires authentication or if SSL or
# TLS is enabled
SENSITIVE_KEYS="${SENSITIVE_KEYS},MAIL_PASSWORD"
MAIL_PASSWORD=

# Indicates type of encryption (none, ssl or tls) should be used to communicate with
# mail server.
MAIL_SMTP_ENCRYPTION=none

# If set to true, sends a message in HTML format.
HTML_MESSAGE_FORMAT=false

# Specifies 'from' address on sent mail in RFC822 format, if supported by mail server.
MAIL_FROM=myovirtengine@mycompany.com

# Specifies 'reply-to' address on sent mail in RFC822 format.
MAIL_REPLY_TO=myusername@mycompany.com

# Interval to send smtp messages per # of IDLE_INTERVAL
MAIL_SEND_INTERVAL=1

# Amount of times to attempt sending an email before failing.
MAIL_RETRIES=4
```

**Note**

For information about the other parameters available for event notification in the ovirt-engine-notifier.conf file, refer to oVirt Documentation.

5. Enable and restart the ovirt-engine-notifier service to activate your changes.

```bash
# systemctl daemon-reload
# systemctl enable ovirt-engine-notifier.service
# systemctl restart ovirt-engine-notifier.service
```

### 2.7.2 Creating Event Notifications in the Administration Portal

Before creating event notifications, you must have access to an email server that can handle incoming automated messages and deliver these messages to a distribution list. You should also configure event notification services on the Engine. For more information, see Section 2.7.1, “Configuring Event Notification Services on the Engine”.

To create event notifications in the Administration Portal:

1. Go to Administration and then click Users.

   The Users pane opens.

2. Under the User Name column, click the name of the user to display the detailed view for the user.
3. Click the Event Notifier tab.

4. Click Manage Events.

   The Add Event Notification dialog box opens.

5. Select the events for which you want to create notifications by selecting the check box next to individual events or event topic areas for notification.

   The events available for notification are grouped under topic areas. By default, selecting the check box for a top-level topic area, such as General Host Events, selects all events under that topic area. You can optionally expand or collapse all the event topic areas by clicking Expand All or Collapse All. Additionally, you can click the arrow icon next to a specific top-level topic area to expand or collapse the events associated with a specific topic area.

6. For the Mail Recipient field, enter an email address.

7. Click OK to save the changes.

### 2.7.3 Canceling Event Notifications in the Administration Portal

To cancel event notifications in the Administration Portal:

1. Go to Administration and then click Users.

   The Users pane opens.

2. Under the User Name column, click the name of the user to display the detailed view for the user.

3. Click the Event Notifier tab.

4. Click Manage Events.

   The Add Event Notification dialog box opens.

5. Click Expand All, or the topic-specific expansion options, to display the events.

6. Clear the appropriate check boxes to cancel the notification for that event.

7. Click OK to save your changes.

### 2.7.4 Configuring the Engine to Send SNMP Traps

You can configure the Manager to send SNMP traps to one or more external SNMP managers. SNMP traps contain system event information that are used to monitor your virtualization environment. The number and type of traps sent to the SNMP manager can be defined within the Engine.

Before performing this task, you must have configured one or more external SNMP managers to receive traps, and know the following details:

- The IP addresses or fully qualified domain names of machines that act as SNMP managers. Optionally, determine the port through which the SNMP manager receives trap notifications; the default UDP port is 162.
The SNMP community. Multiple SNMP managers can belong to a single community. Management systems and agents can communicate only if they are within the same community. The default community is `public`.

The trap object identifier for alerts. The Engine provides a default OID of `1.3.6.1.4.1.2312.13.1.1`. All trap types are sent, appended with event information, to the SNMP manager when this OID is defined.

**Note**
- Changing the default trap prevents generated traps from complying with the Engine’s management information base.
- The Engine provides management information bases at `/usr/share/doc/ovirt-engine/mibs/OVIRT-MIB.txt` and `/usr/share/doc/ovirt-engine/mibs/REDHAT-MIB.txt`. Load the MIBs in your SNMP manager before proceeding.

To configure SNMP traps on the Engine:

1. Log in to the host that is running the Manager.
2. On the Engine, create the SNMP configuration file:

```bash
# vi /etc/ovirt-engine/notifier/notifier.conf.d/20-snmp.conf
```

Default SNMP configuration values exist on the Engine in the events notifications configuration file (`ovirt-engine-notifier.conf`), which is available at the following directory path: `/usr/share/ovirt-engine/services/ovirt-engine-notifier/ovirt-engine-notifier.conf`. The values provided in this step are based on the default or example values provided in that file. To persist that your configuration settings persist across reboots, define an override file for your SNMP configuration (`20-snmp.conf`), rather than edit the `ovirt-engine-notifier.conf` file. For more information, see [Section 2.7.1, “Configuring Event Notification Services on the Engine”](#).

3. Specify the SNMP manager, the SNMP community, and the OID in the following format:

```text
SNMP_MANAGERS="manager1.example.com manager2.example.com:162"
SNMP_COMMUNITY=public
SNMP_OID=1.3.6.1.4.1.2312.13.1.1
```

The following values can be configured in the `20-snmp.conf` file.

```text
#-------------------------#
# SNMP_TRAP Notifications #
#-------------------------#
# Send v2c snmp notifications
# Minimum SNMP configuration
#
# Create /etc/ovirt-engine/notifier/notifier.conf.d/20-snmp.conf with:
# SNMP_MANAGERS="host"
# FILTER="include:*(snmp:) ${FILTER}"
# Default whitespace separated IPv4/[IPv6]/DNS list with optional port, default is 162.
# SNMP_MANAGERS="manager1.example.com manager2.example.com:164"
# SNMP_MANAGERS=
#
# Default SNMP Community String.
SNMP_COMMUNITY=public
```
# SNMP Trap Object Identifier for outgoing notifications.
# { iso(1) org(3) dod(6) internet(1) private(4) enterprises(1) redhat(2312) ovirt(13)
#  \ engine(1) notifier(1) }
#
# Note: changing the default will prevent generated traps from complying with
# OVI RN-MIB.txt.
SNMP_OID=1.3.6.1.4.1.2312.13.1.1
#
# Default SNMP Version. SNMP version 2 and version 3 traps are supported
# 2 = SNMPv2
# 3 = SNMPv3
SNMP_VERSION=2
#
# The engine id used for SNMPv3 traps
SNMP_ENGINE_ID=
#
# The user name used for SNMPv3 traps
SNMP_USERNAME=
#
# The SNMPv3 auth protocol. Supported values are MD5 and SHA.
SNMP_AUTH_PROTOCOL=
#
# The SNMPv3 auth passphrase, used when SNMP_SECURITY_LEVEL is set to AUTH_NOPRIV
# and AUTH_PRIV
SNMP_AUTH_PASSPHRASE=
#
# The SNMPv3 privacy protocol. Supported values are AES128, AES192 and AES256.
# Be aware that AES192 and AES256 are not defined in RFC3826, so please verify
# that your SNMP server supports those protocols before enabling them.
SNMP_PRIVACY_PROTOCOL=
#
# The SNMPv3 privacy passphrase, used when SNMP_SECURITY_LEVEL is set to AUTH_PRIV
SNMP_PRIVACY_PASSPHRASE=
#
# The SNMPv3 security level.
# 1 = NOAUTH_NOPRIV
# 2 = AUTH_NOPRIV
# 3 = AUTH_PRIV
SNMP_SECURITY_LEVEL=1
#
# SNMP profile support
#
# Multiple SNMP profiles are supported.
# Specify profile settings by using _profile suffix,
# for example, to define a profile to sent specific
# message to host3, specify:
# SNMP_MANAGERS_profile1=host3
# FILTER="include:VDC_START(snmp:profile1) ${FILTER}"
4. Define which events to send to the SNMP Manager.

By default, the following default filter is defined in the `ovirt-engine-notifier.conf` file; if you do not override this filter or apply overriding filters, no notifications are sent.

```
FILTER="exclude:\*"
```

The following are other common examples of event filters.

- Send all events to the default SNMP profile.

```
FILTER="include:\*(snmp:) ${FILTER}"
```

- Send all events with the severity `ERROR` or `ALERT` to the default SNMP profile:

```
FILTER="include:\*:ERROR(snmp:) ${FILTER}"
FILTER="include:\*:ALERT(snmp:) ${FILTER}"
```

5. Save the file.

6. Start the `ovirt-engine-notifier` service, and ensure that this service starts on boot.

```
# systemctl start ovirt-engine-notifier.service
# systemctl enable ovirt-engine-notifier.service
```

7. (Optional) Validate that traps are being sent to the SNMP Manager.
Chapter 3 Deployment Optimization

Table of Contents

3.1 Optimizing Clusters, Hosts and Virtual Machines .......................................................... 41
   3.1.1 Configuring Memory and CPUs .................................................................................. 41
   3.1.2 Configuring a Highly Available Host ........................................................................... 44
   3.1.3 Configuring a Highly Available Virtual Machine ....................................................... 46
   3.1.4 Configuring High-Performance Virtual Machines ....................................................... 48
3.2 Hot Plugging Devices on Virtual Machines ......................................................................... 50
   3.2.1 Hot Plugging vCPUs .................................................................................................. 50
   3.2.2 Hot Plugging Virtual Memory .................................................................................... 50

You can configure Oracle Linux Virtualization Manager so that your cluster is optimized and your hosts and virtual machine are highly available. You can also enable or disable devices (hot plug) while a virtual machine is running.

3.1 Optimizing Clusters, Hosts and Virtual Machines

Whether you have a new cluster, host, or virtual machine or existing ones, you can optimize resources such as CPU and memory and configure hosts and virtual machines for high availability.

3.1.1 Configuring Memory and CPUs

Using the Optimization tab when creating or editing a cluster, you can select the memory page sharing threshold for the cluster, and optionally enable CPU thread handling and memory ballooning on the hosts in the cluster. Some of the benefits are:

• Virtual machines run on hosts up to the specified overcommit threshold. Higher values conserve memory at the expense of great CPU usage.

• Hosts to run virtual machines with a total number of CPU cores greater than the number of cores in the host.

• Memory overcommitment on virtual machines running on the hosts in the cluster.

• Memory Overcommitment Manager (MoM) runs Kernel Same-page Merging (KSM) when it can yield a memory saving benefit.

**Note**

If a virtual machine is running Oracle products, such as Oracle Database or other Oracle applications, that require dedicated memory, configuring memory overcommitment is not an available option.

Using the Resource Allocation tab when creating or editing a virtual machine, you can:

• set the maximum amount of processing capability a virtual machine can access on its host.

• pin a virtual CPU to a specific physical CPU.

• guarantee an amount of memory for the virtual machine.

• enable the memory balloon device for the virtual machine. Enable **Memory Balloon Optimization** must also be selected for the cluster.
• improve the speed of disks that have a VirtIO interface by pinning them to a thread separate from the virtual machine's other functions.

3.1.1 Configuring Cluster Memory and CPUs

Use the Administration Portal to optimize the usage of memory and CPUs at the cluster level:

1. Select the Optimization tab of the New Cluster or Edit Cluster window.

2. Choose a setting for Memory Optimization:
   • None - Disable memory overcommit
     Disables memory page sharing, which allows you to commit 100% of the physical memory to virtual machines.
   • For Server Load - Allow scheduling of 150% of physical memory
     Sets memory page sharing threshold to 150% of the system memory on each host.
   • For Desktop Load - Allow scheduling of 200% of physical memory
     Sets memory page sharing threshold to 200% of the system memory on each host.

3. Under CPU Threads, check Count Threads As Cores to allow guests to use host threads as virtual CPU cores.

Allowing hosts to run virtual machines with the total number of processing cores greater than the number of cores in the host may be useful for less CPU-intensive workloads.

4. Under Memory Balloon, check Enable Memory Balloon Optimization to enable memory overcommitment on virtual machines running on hosts in this cluster.

The MoM starts ballooning where and when possible. It is only limited by the guaranteed memory size of every virtual machine. Each virtual machine in the cluster needs to have a balloon device with relevant drivers, which is included unless you specifically remove it. Every host in the cluster receives a balloon policy update when its Status changes to Up.

Note
Enable ballooning on virtual machines that have applications and loads that slowly consume memory, occasionally release memory, or stay dormant for long periods of time, such as virtual desktops.

5. Under KSM Control, check Enable KSM to enable MoM to run KSM when necessary and when it can yield a memory saving benefit that outweighs its CPU cost.

6. Click OK to save your changes.

3.1.1.2 Changing Memory Overcommit Manually

The memory overcommit settings in the Administration Portal allow you to disable overcommit or set it to 150% or 200%. If you require a different value for your cluster, you can change the setting manually.

1. From a command line, log into the Engine.

2. Check the current memory overcommit settings:

```
# engine-config -a | grep -i maxvdsmem
```

42
3. Change the memory overcommit settings:

```bash
# engine-config -s MaxVdsMemOverCommitForServers=percentage
# engine-config -s MaxVdsMemOverCommit=percentage
```

### 3.1.1.3 Configuring Virtual Machine Memory and CPUs

To optimize the usage of memory and CPUs for a virtual machine:

1. Select the **Resource Allocation** tab of the **New VM** or **Edit VM** window.

2. Under **CPU Allocation**, for the **CPU Shares** drop-down list select the level of CPU resources a virtual machine can demand relative to other virtual machines in the cluster.

   - **Low** = 512
   - **Medium** = 1024
   - **High** = 2048
   - **Custom** = Enter a number in the field next to the drop-down list

3. Under **Memory Allocation**, for **Physical Memory Guaranteed** enter an amount of memory.

   The amount of physical memory guaranteed for a virtual machine should be any number between 0 and its defined memory.

4. Check **Memory Balloon Device Enabled** to enable the device for the virtual machine and allow memory overcommitment.

   **Important**
   
   Since this check box is selected by default, make sure you have enabled memory ballooning for the cluster where the virtual machine's host resides.

5. Under **I/O Threads**, check **I/O Threads Enabled** to improve the speed of disks that have a VirtIO interface by pinning them to a thread separate from the virtual machine's other functions.

   This check box is selected by default.

6. Under **Queues**, check **Multi Queues Enabled** to create up to four queues per vNIC, depending on how many vCPUs are available.

   This check box is selected by default.

   To define a different number of queues per vNIC, you can create a custom property:

   ```bash
   # engine-config -s "CustomDeviceProperties={type=interface;prop={other-nic-properties;queues=[1-9][0-9]}}"
   ```

   where **other-nic-properties** is a list of pre-existing NIC custom properties separated by semicolons.

7. Under **Queues**, check **VirtIO-SCSI Enabled** to enable or disable the use of VirtIO-SCSI on the virtual machine.

   This check box is selected by default.
8. Click **OK** to save your changes.

### 3.1.2 Configuring a Highly Available Host

If you want the hosts in a cluster to be responsive and available when unexpected failures happen, you should use fencing. Fencing allows a cluster to react to unexpected host failures and enforce power saving, load balancing, and virtual machine availability policies. You should configure the fencing parameters for your host’s power management device and test their correctness from time to time.

A **Non Operational** host is different from a **Non Responsive** host. A **Non Operational** host can communicate with the Manager, but has incorrect configuration, for example a missing logical network. A **Non Responsive** host cannot communicate with the Manager.

In a fencing operation, a non-responsive host is rebooted, and if the host does not return to an active status within a prescribed time, it remains non-responsive pending manual intervention and troubleshooting.

The Manager can perform management operations after it reboots, by a proxy host, or manually in the **Administration Portal**. All the virtual machines running on the non-responsive host are stopped, and highly available virtual machines are restarted on a different host. At least two hosts are required for power management operations.

#### Important

If a host runs virtual machines that are highly available, power management must be enabled and configured.

### 3.1.2.1 Configuring Power Management and Fencing on a Host

The Manager uses a proxy to send power management commands to a host power management device because the engine does not communicate directly with fence agents. The host agent (VDSM) executes power management device actions and another host in the environment is used as a fencing proxy. This means that you must have at least two hosts for power management operations.

When you configure a fencing proxy host, make sure the host is in:

- the same cluster as the host requiring fencing.
- the same data center as the host requiring fencing.
- **UP** or **Maintenance** status to remain viable.

Power management operations can be performed in three ways:

- by the Manager after it reboots
- by a proxy host
- manually in the **Administration Portal**

To configure power management and fencing on a host:

1. Click **Compute** and select **Hosts**.
2. Select a host and click **Edit**.
3. Click the **Power Management** tab.
4. Check **Enable Power Management** to enable the rest of the fields.

5. Check **Kdump integration** to prevent the host from fencing while performing a kernel crash dump. Kdump integration is enabled by default.

   ![Important]
   
   If you enable or disable Kdump integration on an existing host, you must reinstall the host.

6. **(Optional)** Check **Disable policy control of power management** if you do not want your host’s power management to be controlled by the scheduling policy of the host’s cluster.

7. To configure a fence agent, click the plus sign (+) next to **Add Fence Agent**.

   The **Edit fence agent** pane opens.

8. Enter the **Address** (IP Address or FQDN) to access the host's power management device.

9. Enter the **User Name** and **Password** of the of the account used to access the power management device.

10. Select the power management device **Type** from the drop-down list.

11. Enter the **Port** (SSH) number used by the power management device to communicate with the host.

12. Enter the **Slot** number used to identify the blade of the power management device.

13. Enter the **Options** for the power management device. Use a comma-separated list of key-value pairs.

   - If you leave the **Options** field blank, you are able to use both IPv4 and IPv6 addresses
   - To use only IPv4 addresses, enter `inet4_only=1`
   - To use only IPv6 addresses, enter `inet6_only=1`

14. Check **Secure** to enable the power management device to connect securely to the host.

   You can use ssh, ssl, or any other authentication protocol your power management device supports.

15. Click **Test** to ensure the settings are correct and then click **OK**.

   **Test Succeeded, Host Status is: on** displays if successful.

   ![Warning]
   
   Power management parameters (userid, password, options, etc.) are tested by the Manager only during setup and manually after that. If you choose to ignore alerts about incorrect parameters, or if the parameters are changed on the power management hardware without changing in the Manager as well, fencing is likely to fail when most needed.

16. Fence agents are sequential by default. To change the sequence in which the fence agents are used:

   a. Review your fence agent order in the **Agents by Sequential Order** field.

   b. To make two fence agents concurrent, next to one fence agent click the **Concurrent with** drop-down list and select the other fence agent.
You can add additional fence agents to this concurrent fence agent group.

17. Expand the **Advanced Parameters** and use the up and down buttons to specify the order in which the Manager searches the host’s **cluster** and **dc** (data center) for a power management proxy.

18. To add an additional power management proxy:
   
a. Click the plus sign (+) next to **Add Power Management Proxy**.

   The **Select fence proxy preference type to add** pane opens.

b. Select a power management proxy from the drop-down list and then click **OK**.

Your new proxy displays in the **Power Management Proxy Preference** list.

---

**Note**

By default, the Manager searches for a fencing proxy within the same cluster as the host. If The Manager cannot find a fencing proxy within the cluster, it searches the data center.

19. Click **OK**.

From the list of hosts, the exclamation mark next to the host’s name disappeared, signifying that you have successfully configured power management and fencing.

### 3.1.2.2 Preventing Host Fencing During Boot

After you configure power management and fencing, when you start the Manager it automatically attempts to fence non-responsive hosts that have power management enabled *after* the quiet time (5 minutes by default) has elapsed. You can opt to extend the quiet time to prevent, for example, a scenario where the Manager attempts to fence hosts while they boot up. This can happen after a data center outage because a host’s boot process is normally longer than the Manager boot process.

You can configure quiet time using the `engine-config` command option `DisableFenceAtStartupInSec`:

```
# engine-config -s DisableFenceAtStartupInSec=<number>
```

### 3.1.2.3 Checking Fencing Parameters

To automatically check the fencing parameters, you can configure the `PMHealthCheckEnabled` (false by default) and `PMHealthCheckIntervalInSec` (3600 sec by default) engine-config options.

```
# engine-config -s PMHealthCheckEnabled=True
# engine-config -s PMHealthCheckIntervalInSec=<number>
```

When set to true, `PMHealthCheckEnabled` checks all host agents at the interval specified by `PMHealthCheckIntervalInSec` and raises warnings if it detects issues.

### 3.1.3 Configuring a Highly Available Virtual Machine

If you have virtual machines that run critical workloads, you might consider configuring these virtual machines for high availability. Only a highly available virtual machine automatically restarts on its original host or migrates to another host in the cluster if its original host:
• has a hardware failure and becomes non-operational.
• has scheduled downtime and is put in maintenance mode.
• loses communication with external storage and becomes unavailable.

If a virtual machine’s host is manually shut down, the virtual machine does not automatically migrate to another host. Further, virtual machines that share the same storage domain can live migrate between hosts that belong to the same cluster. For more information, see *Migrating Virtual Machines between Hosts* in the *Oracle Linux Virtualization Manager: Administration Guide*.

**Note**

A highly available virtual machine does not restart if you shut it down cleanly from within the virtual machine or the Manager or if you shut down a host without first putting it into maintenance mode.

To enable a virtual machine to migrate to another available host in the cluster:
• Configure power management and fencing for the host running the highly available virtual machine
• Ensure the highly available virtual machine’s host is part of a cluster of two or more available hosts
• Check that the destination host is operational
• Ensure the source and destination hosts can access the data domain where the virtual machine resides
• Ensure the source and destination hosts can access the same virtual networks and VLANs
• Check that the destination host has enough RAM and CPUs that are not in use to support the virtual machine’s requirements

Virtual machines can also be restarted on another host even if the original host loses power if you have configured it to acquire a lease on a special volume on the storage domain. Acquiring a lease prevents the virtual machine from being started on two different hosts, which could result in virtual machine disk corruption.

If you configure high availability:
• there is minimal service interruption because virtual machines are restarted within seconds and with no user intervention.
• your resources are balanced by restarting virtual machines on a host with low current resource utilization.
• you are ensured that there is sufficient capacity to restart virtual machines at all times.

You must configure high availability for each virtual machine using the following steps:
1. Click **Compute** and then **Virtual Machines**.
2. In the list of virtual machines, click to highlight a virtual machine and then click **Edit**.
3. In the **Edit Virtual Machine** window, click the **High Availability** tab.
4. Check **Highly Available** to enable high availability for the virtual machine.
5. From the **Target Storage Domain for VM Lease** drop-down list, select **No VM Lease** (default) to disable the functionality or select a storage domain to hold the virtual machine lease.
Virtual machines are able to acquire a lease on a special volume on the storage domain. This enables a virtual machine to start on another host even if the original host loses power. For more information, see Storage Leases in the Oracle Linux Virtualization Manager: Architecture and Planning Guide.

6. From the Resume Behavior drop-down list, select AUTO_RESUME, LEAVE_PAUSED, OR KILL. If you defined a VM lease, KILL is the only option available.

7. From the Priority list, select Low, Medium, or High.

When virtual machine migration is triggered, a queue is created in which the high priority virtual machines are migrated first. If a cluster is running low on resources, only the high-priority virtual machines are migrated.

8. Click OK.

3.1.4 Configuring High-Performance Virtual Machines

You can configure a virtual machine for high performance, so that it runs with performance metrics as close to bare metal as possible. When you choose high performance optimization, the virtual machine is configured with a set of automatic, and recommended manual, settings for maximum efficiency.

The high performance option is only accessible in the Administration Portal, by selecting High Performance from the Optimized for dropdown list in the Edit or New virtual machine, template, or pool window. This option is not available in the VM Portal.

If you change the optimization mode of a running virtual machine to high performance, some configuration changes require restarting the virtual machine. To change the optimization mode of a new or existing virtual machine to high performance, you may need to make manual changes to the cluster and to the pinned host configuration first.

A high performance virtual machine has certain limitations, because enhanced performance has a trade-off in decreased flexibility:

- If pinning is set for CPU threads, IO threads, emulator threads, or NUMA nodes, according to the recommended settings, only a subset of cluster hosts can be assigned to the high performance virtual machine.

- Many devices are automatically disabled, which limits the virtual machine’s usability.

3.1.4.1 Creating a High Performance Virtual Machine

To create a high performance virtual machine:

1. In the New or Edit window, select High Performance from the Optimized for drop-down menu.

   Selecting this option automatically performs certain configuration changes to this virtual machine.

2. Click OK.

   If you have not set any manual configurations, the High Performance Virtual Machine/Pool Settings screen describing the recommended manual configurations appears.

   If you have set some of the manual configurations, the High Performance Virtual Machine/Pool Settings screen displays the settings you have not made.

   If you have set all the recommended manual configurations, the High Performance Virtual Machine/Pool Settings screen does not appear.
3. If the **High Performance Virtual Machine/Pool Settings** screen appears, click **Cancel** to return to the **New** or **Edit** window to perform the manual configurations. For details, see *Configuring the Recommended Manual Settings* in *oVirt Documentation*.

Alternatively, click **OK** to ignore the recommendations. The result may be a drop in the level of performance.

4. Click **OK**.

You can view the optimization type in the **General** tab of the details view of the virtual machine, pool, or template.

Certain configurations can override the high performance settings. For example, if you select an instance type for a virtual machine before selecting **High Performance** from the **Optimized for** drop-down menu and performing the manual configuration, the instance type configuration will not affect the high performance configuration. If, however, you select the instance type after the high performance configurations, you should verify the final configuration in the different tabs to ensure that the high performance configurations have not been overridden by the instance type.

The last-saved configuration usually takes priority.

### 3.1.4.2 Configuring Huge Pages

You can configure a virtual machine for high performance, so that it runs with performance metrics as close to bare metal as possible. When you choose high performance optimization, the virtual machine is configured with a set of automatic and recommended manual settings for maximum efficiency. By using huge pages, you increase the page size which reduces the page table, reduces the pressure on the Translation Lookaside Buffer cache, and improves performance.

Huge pages are pre-allocated when a virtual machine starts to run (dynamic allocation is disabled by default).

![Note]

If you configure huge pages for a virtual machine, you cannot hotplug or hot uplug memory.

To configure huge pages:

1. In the **Custom Properties** tab, select **hugepages** from the custom properties list, which displays **Please select a key**... by default.

2. Enter the huge page size in KB.

   You should set the huge page size to the largest size supported by the pinned host. The recommended size for x86_64 is 1 GB.

   The huge page size has the following requirements:

   • The virtual machine’s huge page size must be the same size as the pinned host’s huge page size.
   • The virtual machine’s memory size must fit into the selected size of the pinned host’s free huge pages.
   • The NUMA node size must be a multiple of the huge page’s selected size.

To enable dynamic allocation of huge pages:
1. Disable the HugePages filter in the scheduler.

2. In the [performance] section in /etc/vdsm/vdsm.conf set the following:

   use_dynamic_hugepages = true

3.2 Hot Plugging Devices on Virtual Machines

You can enable or disable devices while a virtual machine is running.

3.2.1 Hot Plugging vCPUs

Hot plugging vCPUs means enabling or disabling devices while a virtual machine is running.

**Note**

Hot unplugging a vCPU is only supported if the vCPU was previously hot plugged. A virtual machine’s vCPUs cannot be hot unplugged to less vCPUs than it was originally created with.

Before you can hot plug vCPUs, you must meet the following prerequisites:

- The virtual machine’s operating system must be explicitly set and must support CPU hot plug. For details, see oVirt Documentation.
- Windows virtual machines must have the guest agents installed.

To hot plug a vCPU:

1. Click Compute and then select Virtual Machines.
2. Select a virtual machine that is running and click Edit.
3. Click the System tab.
4. Change the value of Virtual Sockets as required.
5. Click OK.

3.2.2 Hot Plugging Virtual Memory

Hot plugging memory means enabling or disabling devices while a virtual machine is running. Each time you hot plug memory, it appears as a new memory device under Vm Devices on the virtual machine's details page, up to a maximum of 16.

When you shut down and restart a virtual machine, these devices are cleared from Vm Devices without reducing the virtual machine’s memory, allowing you to hot plug more memory devices.

**Note**

This feature is only available for the self-hosted engine Engine virtual machine, which is currently a technology preview feature.

To hot plug virtual memory:

1. Click Compute and then select Virtual Machines.
2. Select a virtual machine that is running and click **Edit**.

3. Click the **System** tab.

4. Enter a new number for **Memory Size**. You can add memory in multiples of 256 MB. By default, the maximum memory allowed for the virtual machine is set to 4x the memory size specified.

5. Click **OK**.

   The **Pending Virtual Machine changes** window opens.

6. Click **OK** for the changes to take place immediately or check **Apply later** and then **OK** to wait for the next virtual machine restart.

7. Click **OK**.

   You can see the virtual machine’s updated memory in the **Defined Memory** field of the virtual machine's details page and you can see the added memory under **Vm Devices**.

You can also hot unplug virtual memory, but consider:

- Only memory added with hot plugging can be hot unplugged.
- The virtual machine’s operating system must support memory hot unplugging.
- The virtual machine must not have a memory balloon device enabled.

To hot unplug virtual memory:

1. Click **Compute** and then select **Virtual Machines**.

2. Click on the name of a virtual machine that is running.

   The virtual machine’s details page opens.

3. Click **Vm Devices**.

4. In the **Hot Unplug** column, click **Hot Unplug** beside any memory device you want to remove.

   The **Memory Hot Unplug** windows opens with a warning.

5. Click **OK**.

   Under **General** on the virtual machine details page, the **Physical Memory Guaranteed** value for the virtual machine is decremented automatically.

  4.2.7 Testing the Active-Passive Configuration ......................................... 61
  4.2.8 Mapping File Attributes .................................................................. 64

Oracle Linux Virtualization Manager supports active-active and active-passive disaster recovery solutions to ensure that environments can recover when a site outage occurs. Both solutions support two sites and require replicated storage.

Active-Active Disaster Recovery

Active-active disaster recovery uses a stretch cluster configuration. This means that there is a single Oracle Linux Virtualization Manager environment with a cluster that contains hosts capable of running the required virtual machines in the primary and secondary site. The virtual machines in the primary site automatically migrate to hosts in the secondary site if an outage occurs. However, the environment must meet latency and networking requirements.

Active-Passive Disaster Recovery

Active-passive disaster recovery is a site-to-site failover solution. Two separate Oracle Linux Virtualization Manager environments are configured: the active primary environment and the passive secondary (backup) environment. With active-passive disaster recovery, you must manually execute failover and failback (when needed) both of which are performed using Ansible.

4.1 Active-Active Disaster Recovery

Oracle Linux Virtualization Manager supports an active-active disaster recovery failover configuration that can span two sites, both of which are active. If the primary site becomes unavailable, the Oracle Linux Virtualization Manager environment smoothly transitions to the secondary site to ensure business continuity.

To support active-active failover, you must configure a stretch cluster where hosts capable of running all the virtual machines in the cluster are located in the primary and secondary site. All the hosts belong to the same Oracle Linux Virtualization Manager cluster. You can implement a stretched cluster configuration using a self-hosted engine environment or a standalone Engine environment.

With active-active disaster recovery you must also have replicated storage that is writable on both sites. This enables virtual machines to migrate between sites and continue running on the site’s storage.
Network Considerations

Virtual machines migrate to the secondary site if the primary site becomes unavailable. When the primary site becomes available and the storage is replicated in both sites, virtual machines automatically failback.

To ensure virtual machine failover and failback works, you must configure:

• virtual machines for highly availability, and each virtual machine must have a lease on a target storage domain to ensure the virtual machine can start even without power management.

• soft enforced virtual machine to host affinity to ensure the virtual machines only start on the selected hosts.

4.1.1 Network Considerations

All hosts in the stretch cluster must be on the same broadcast domain over a Layer 2 (L2) network, which means that connectivity between the two sites needs to be L2.

The maximum latency requirements between the sites across the L2 network is different for the standalone Engine environment and the self-hosted engine environment:

• A maximum latency of 100ms is required for the standalone Engine environment

• A maximum latency of 7ms is required for self-hosted engine environment

4.1.2 Storage Considerations

The storage domain for Oracle Linux Virtualization Manager can be either block devices (iSCSI or FCP) or a file system (NAS/NFS or GlusterFS).

Both sites require synchronously replicated storage that is writable with shared L2 network connectivity to allow virtual machines to migrate between sites and continue running on the site’s storage. All storage replication options supported by Oracle Linux 7 and later can be used in the stretch cluster.

For more information, see the storage topics in the Administration Guide and the Architecture and Planning Guide.

4.1.3 Configuring a Standalone Engine Stretch Cluster Environment

Before you begin configuring your standalone engine environment for a stretch cluster, review the following prerequisites and limitations:

• A writable storage server in both sites with L2 network connectivity.

• Real-time storage replication service to duplicate the storage.

• Maximum 100ms latency between sites.

The Engine must be highly available for virtual machines to failover and failback between sites. If the Engine goes down with the site, the virtual machines do not failover.

• The standalone Engine is only highly available when managed externally, for example:

• As a highly available virtual machine in a separate virtualization environment

• In a public cloud

To configure a standalone engine stretch cluster:
1. Install and configure the Oracle Linux Virtualization Manager engine.
   For more information, see Installation and Configuration.

2. Install hosts in each site and add them to the cluster.
   For more information, see Configuring a KVM Host.

3. Configure the storage pool manager (SPM) priority to be higher on all hosts in the primary site to ensure SPM failover to the secondary site occurs only when all hosts in the primary site are unavailable.
   For more information, see Storage Pool Manager.

4. Configure all virtual machines that need to failover as highly available and ensure that a virtual machine has a lease on the target storage domain.
   For more information, see Section 3.1, “Optimizing Clusters, Hosts and Virtual Machines”.

5. Configure virtual machine to host soft affinity and define the behavior you expect from the affinity group.
   For more information, see Affinity Groups in the oVirt Virtual Machine Management Guide.

   ! Important

   With VM Affinity Rule Enforcing enabled (shown as Hard in the list of Affinity Groups), the system does not migrate a virtual machine to a host different from where the other virtual machines in its affinity group are running. For more information, see Virtual Machine Issues.

The active-active failover can be manually performed by placing the main site’s hosts into maintenance mode.

4.4 Configuring a Self-Hosted Engine Stretch Cluster Environment

Before you begin configuring your self-hosted engine environment for a stretch cluster, review the following prerequisites and limitations:

• A writable storage server in both sites with L2 network connectivity
• Real-time storage replication service to duplicate the storage
• Maximum 7ms latency between sites

To configure a self-hosted engine stretch cluster:

1. Deploy the Oracle Linux Virtualization Manager self-hosted engine.
   For more information, see Self-hosted Engine Deployment.

2. Optionally, install additional hosts in each site and add them to the cluster.
   For more information, see Adding a KVM Host.

3. Configure the storage pool manager (SPM) priority to be higher on all hosts in the primary site to ensure SPM failover to the secondary site occurs only when all hosts in the primary site are unavailable.
For more information, see Storage Pool Manager.

4. Configure all virtual machines that need to failover as highly available and ensure that a virtual machine has a lease on the target storage domain.

For more information, see Section 3.1, “Optimizing Clusters, Hosts and Virtual Machines”.

5. Configure a virtual machine to host soft affinity and define the affinity group’s behaviour.

For more information, see Affinity Groups in the oVirt Virtual Machine Management Guide.

![Important]

With VM Affinity Rule Enforcing enabled (shown as Hard in the list of Affinity Groups), the system does not migrate a virtual machine to a host different from where the other virtual machines in its affinity group are running. For more information, see Virtual Machine Issues.

The active-active failover can be manually performed by placing the main site’s hosts into maintenance mode.

### 4.2 Active-Passive Disaster Recovery

Oracle Linux Virtualization Manager active-passive disaster recovery solution can span two sites. If the primary site becomes unavailable, the Oracle Linux Virtualization Manager environment can be forced to failover to the secondary (backup) site.

Failover is achieved by configuring a secondary site with:

- An active Oracle Linux Virtualization Manager Engine.
- A data center and clusters.
- Networks with the same general connectivity as the primary site.
- Active hosts capable of running critical virtual machines after failover.

![Important]

You must ensure that the secondary environment has enough resources to run the failed over virtual machines, and that both the primary and secondary environments have identical Engine versions, data center and cluster compatibility levels, and PostgreSQL versions.

Storage domains that contain virtual machine disks and templates in the primary site must be replicated. These replicated storage domains must not be attached to the secondary site.

The failover and failback processes are executed manually using Ansible playbooks that map entities between the sites and manage the failover and failback processes. The mapping file instructs the Oracle Linux Virtualization Manager components where to failover or failback to.

### 4.2.1 Network Considerations

You must ensure that the same general connectivity exists in the primary and secondary sites. If you have multiple networks or multiple data centers then you must use an empty network mapping in the mapping file to ensure that all entities register on the target during failover.
4.2.2 Storage Considerations

The storage domain for Oracle Linux Virtualization Manager can be made of either block devices (iSCSI or FCP) or a file system (NAS/NFS or GlusterFS). Local storage domains are unsupported for disaster recovery.

Your environment must have a primary and secondary storage replica. The primary storage domain’s block devices or shares that contain virtual machine disks or templates must be replicated. The secondary storage must not be attached to any data center and is added to the backup site’s data center during failover.

If you are implementing disaster recovery using a self-hosted engine, ensure that the storage domain used by the self-hosted engine’s Engine virtual machine does not contain virtual machine disks because the storage domain will not failover.

You can use any storage solutions that have replication options supported by Oracle Linux 7 and later.

Important

Metadata for all virtual machines and disks resides on the storage data domain as OVF_STORE disk images. This metadata is used when the storage data domain is moved by failover or failback to another data center in the same or different environment.

By default, the metadata is automatically updated by the Engine in 60 minute intervals. This means that you can potentially lose all data and processing completed during an interval. To avoid such loss, you can manually update the metadata from the Administration Portal by navigating to the storage domain section and clicking Update OVFs. Or, you can modify the Engine parameters to change the update frequency, for example:

```
# engine-config --s OvfUpdateIntervalInMinutes=30 && systemctl restart ovirt-engine
```

For more information, see the storage topics in the Administration Guide and the Architecture and Planning Guide.

4.2.3 Creating the Ansible Playbooks

You use Ansible to initiate and manage the active-passive disaster recovery failover and failback through Ansible playbooks that you create. For more information about Ansible playbooks, see the Ansible documentation.

Before you begin creating your Ansible playbooks, review the following prerequisites and limitations:

- Primary site has a fully functioning Oracle Linux Virtualization Manager environment.
- A backup environment in the secondary site with the same data center and cluster compatibility level as the primary environment. The backup environment must have:
  - An Oracle Linux Virtualization Manager Engine
  - Active hosts capable of running the virtual machines and connecting to the replicated storage domains
  - A data center with clusters
  - Networks with the same general connectivity as the primary site
Creating the Ansible Playbooks

- Replicated storage that contains virtual machines and templates not attached to the secondary site.
- The `ovirt.disaster-recovery` package must be installed on the highly available Ansible Engine machine to automate the failover and failback.
- The machine running the Ansible Engine must be able to use SSH to connect to the Engine in the primary and secondary site.

**Note**

We recommend that you create environment properties that exist in the primary site, such as affinity groups, affinity labels, users, on the secondary site. The default behaviour of the Ansible playbooks can be configured in the `/usr/share/ansible/roles/ovirt.disaster-recovery/defaults/main.yml` file.

You must create the following required Ansible playbooks:

- Playbook that creates the file to map entities on the primary and secondary sites
- Failover playbook
- Failback playbook

The playbooks and associated files that you create must reside in `/usr/share/ansible/roles/ovirt.disaster-recovery/` on the Ansible machine that is managing the failover and failback. If you have multiple Ansible machines that can manage it, ensure that you copy the files to all of them.

After configuring active-passive disaster recovery, you should test and verify the configuration. See Section 4.2.7, "Testing the Active-Passive Configuration".

### 4.2.3.1 Simplifying Ansible Tasks Using the `ovirt-dr` Script

You can use the `ovirt-dr` script, located in `/usr/share/ansible/roles/ovirt.disaster-recovery/files`, to simplify these Ansible tasks:

- Generating a `var` mapping file of the primary and secondary sites for failover and fallback
- Validating the `var` mapping file
- Executing failover on a target site
- Executing failback from a target site to a source site

The following is an example of the `ovirt-dr` script:

```
# ./ovirt-dr generate/validate/failover/failback
[--conf-file=dr.conf]
[--log-file=ovirt-dr-log_number.log]
[--log-level=DEBUG/INFO/WARNING/ERROR]
```

You optionally can make the following customizations:

- Set parameters for the script’s actions in the configuration file: `/usr/share/ansible/roles/ovirt.disaster-recovery/files/dr.conf`.
- Change location of the configuration file using the `--conf-file` option
- Set location of log file using the `--log-file` option
- Set level of logging detail using the `--log-level` option
4.2.3.2 Generating the Mapping File Using an Ansible Playbook

The Ansible playbook used to generate the mapping file prepopulates the file with the primary site’s entities. Then, you need to manually add to the file the backup site’s entities, such as IP addresses, cluster, affinity groups, affinity label, external LUN disks, authorization domains, roles, and vNIC profiles.

**Important**

Generating the mapping file will fail if you have any virtual machine disks on the self-hosted engine’s storage domain. Also, the generated mapping file will not contain an attribute for this storage domain because it must not be failed over.

To create the mapping file, complete the following steps.

1. Create an Ansible playbook using a yaml file (such as `dr-olvm-setup.yml`) to generate the mapping file. For example:

   ```yaml
   ---
   - name: Generate mapping
     hosts: localhost
     connection: local

     vars:
       site: https://example.engine.com/ovirt-engine/api
       username: admin@internal
       password: my_password
       ca: /etc/pki/ovirt-engine/ca.pem
       var_file: disaster_recovery_vars.yml

     roles:
     - oVirt.disaster-recovery
   
   For extra security you can encrypt your Engine password in a `.yml` file.

2. Run the Ansible command to generate the mapping file. The primary site’s configuration will be prepopulated.

   ```bash
   # ansible-playbook dr-olvm-setup.yml --tags "generate_mapping"
   
   3. Configure the generated mapping `.yml` file with the backup site’s configuration. For more information, see Section 4.2.8, "Mapping File Attributes".

   If you have multiple Ansible machines that can perform failover and failback, then copy the mapping file to all relevant machines.

4.2.3.3 Creating Failover and Failback Playbooks

Before creating the failover and failback playbooks, ensure you have created and configured the mapping file, which must be added to the playbooks.

To create the failover and failback playbooks, complete the following steps.

1. Optionally, define a password file (for example `passwords.yml`) to store the Engine passwords of the primary and secondary site, for example:

   ```yaml
   # This file is in plain text, if you want to encrypt this file, please execute following command:
   
   # $ ansible-vault encrypt passwords.yml
   ```
Executing a Failover

# It will ask you for a password, which you must then pass to
# ansible interactively when executing the playbook.
#
# $ ansible-playbook myplaybook.yml --ask-vault-pass

#
dr_sites_primary_password: primary_password
dr_sites_secondary_password: secondary_password

For extra security you can encrypt the password file. However, you will need to use the \texttt{--ask-vault-pass} parameter when running the playbook.

2. Create an Ansible playbook using a failover yaml file (such as dr-olvm-failover.yml) to failover the environment, for example:

```yaml
- name: Failover OLVM
  hosts: localhost
  connection: local
  vars:
    dr_target_host: secondary
    dr_source_map: primary
  vars_files:
    - disaster_recovery_vars.yml
    - passwords.yml
  roles:
    - oVirt.disaster-recovery
```

3. Create an Ansible playbook using a failback yaml file (such as dr-olvm-failback.yml) to failback the environment, for example:

```yaml
- name: Failback OLVM
  hosts: localhost
  connection: local
  vars:
    dr_target_host: primary
    dr_source_map: secondary
  vars_files:
    - disaster_recovery_vars.yml
    - passwords.yml
  roles:
    - oVirt.disaster-recovery
```

4.2.4 Executing a Failover

Before executing a failover, ensure you have read and understood the Section 4.2.1, “Network Considerations” and Section 4.2.2, “Storage Considerations”. You must also ensure that:

- the Engine and hosts in the secondary site are running.
- replicated storage domains are in read/write mode.
- no replicated storage domains are attached to the secondary site.
- a machine running the Ansible Engine that can connect via SSH to the Engine in the primary and secondary site, with the required packages and files:
  - The oVirt.disaster-recovery package.
  - The mapping file and failover playbook.

Sanlock must release all storage locks from the replicated storage domains before the failover process starts. These locks should be released automatically approximately 80 seconds after the disaster occurs.
To execute a failover, run the failover playbook on the Engine host using the following command:

```
# ansible-playbook dr-olvm-failover.yml --tags "fail_over"
```

When the primary site becomes active, ensure that you clean the environment before failing back. For more information, see Section 4.2.5, “Cleaning the Primary Site”.

### 4.2.5 Cleaning the Primary Site

After you failover, you must clean the environment in the primary site before failing back to it. Cleaning the primary site's environment:

- Reboots all hosts in the primary site.
- Ensures the secondary site's storage domains are in read/write mode and the primary site's storage domains are in read only mode.
- Synchronizes the replication from the secondary site's storage domains to the primary site's storage domains.
- Cleans the primary site of all storage domains to be imported. This can be done manually in the Engine. For more information, see *Detaching a Storage Domain from a Data Center*.

Once you have cleaned the primary site, you can now failback the environment to the primary site. For more information, see Section 4.2.6, “Executing a Failback”.

### 4.2.6 Executing a Failback

After failover, you can failback to the primary site when it is active and you have performed the necessary steps to clean the environment by ensuring:

- The primary site's environment is running and has been cleaned. For more information, see Section 4.2.5, “Cleaning the Primary Site”.
- The environment in the secondary site is running and has active storage domains.
- The machine running the Ansible Engine that can connect via SSH to the Engine in the primary and secondary site, with the required packages and files:
  - The `ovirt.disaster-recovery` package.
  - The mapping file and required failback playbook.

To execute a failback, complete the following steps.

1. Run the failback playbook on the Engine host using the following command:

   ```
   # ansible-playbook dr-olvm-failback.yml --tags "fail_back"
   ```

2. Enable replication from the primary storage domains to the secondary storage domains.

### 4.2.7 Testing the Active-Passive Configuration

You must test your disaster recovery solution after configuring it using one of the provided options:

1. Test failover while the primary site remains active and without interfering with virtual machines on the primary site's storage domains. See Section 4.2.7.1, “Discreet Failover Test”.

---

61
2. Test failover and failback using specific storage domains attached to the primary site which allows the primary site to remain active. See Section 4.2.7.2, “Discreet Failover and Failback Tests”.

3. Test failover and failback for an unplanned shutdown of the primary site or an impending disaster where you have a grace period to failover to the secondary site. See Section 4.2.7.3, “Full Failover and Failback Tests”.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure that you have completed all the steps to configure your active-passive disaster recovery before running any of these tests.</td>
</tr>
</tbody>
</table>

### 4.2.7.1 Discreet Failover Test

The discreet failover test simulates a failover while the primary site and all its storage domains remain active which allows users to continue working in the primary site. To perform this test, you must disable replication between the primary storage domains and the replicated (secondary) storage domains. During this test the primary site is unaware of the failover activities on the secondary site.

This test does not allow you to test the failback functionality.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure that no production tasks are performed after the failover. For example, ensure that email systems are blocked from sending emails to real users or redirect emails elsewhere. If systems are used to directly manage other systems, prohibit access to the systems or ensure that they access parallel systems in the secondary site.</td>
</tr>
</tbody>
</table>

To perform a discreet failover test, complete the following steps.

1. Disable storage replication between the primary and replicated storage domains and ensure that all replicated storage domains are in read/write mode.

2. Run the following command to failover to the secondary site:

```
# ansible-playbook playbook --tags "fail_over"
```

3. Verify that all relevant storage domains, virtual machines, and templates are registered and running successfully on the secondary site.

To restore the environment to its active-passive state, complete the following steps.

1. Detach the storage domains from the secondary site.

2. Enable storage replication between the primary and secondary storage domains.

### 4.2.7.2 Discreet Failover and Failback Tests

The discreet failover and failback tests use testable storage domains that you specifically define for testing failover and failback. These storage domains must be replicated so that the replicated storage can be attached to the secondary site which allows you to test the failover while users continue to work in the primary site.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>You should define the testable storage domains on a separate storage server that can be offline without affecting the primary storage domains used for production in the primary site.</td>
</tr>
</tbody>
</table>
To perform a discreet failover test, complete the following steps.

1. Stop the test storage domains in the primary site. For example, shut down the server host or block it with a firewall rule.

2. Disable the storage replication between the testable storage domains and ensure that all replicated storage domains used for the test are in read/write mode.

3. Place the test primary storage domains into read-only mode.

4. Run the command to failover to the secondary site:
   
   ```bash
   # ansible-playbook playbook --tags "fail_over"
   ```

5. Verify that all relevant storage domains, virtual machines, and templates are registered and running successfully on the secondary site.

To perform a discreet failback test, complete the following steps.

1. Clean the primary site and remove all inactive storage domains and related virtual machines and templates. For more information, see Section 4.2.5, “Cleaning the Primary Site”.

2. Run the command to failback to the primary site:
   
   ```bash
   # ansible-playbook playbook --tags "fail_back"
   ```

3. Enable replication from the primary storage domains to the secondary storage domains.

4. Verify that all relevant storage domains, virtual machines, and templates are registered and running successfully in the primary site.

### 4.2.7.3 Full Failover and Failback Tests

The full failover and failback tests allow you to simulate a primary site disaster, failover to the secondary site, and failback to the primary site. To simulate a primary site disaster, you can shut down the primary site’s hosts or by add firewall rules to block writing to the storage domains.

To perform a full failover test, complete the following steps.

1. Disable storage replication between the primary and replicated storage domains and ensure that all replicated storage domains are in read/write mode.

2. Run the command to failover to the secondary site:
   
   ```bash
   # ansible-playbook playbook --tags "fail_over"
   ```

3. Verify that all relevant storage domains, virtual machines, and templates are registered and running successfully in the secondary site.

To perform a full failback test, complete the following steps.

1. Synchronize replication between the secondary site’s storage domains and the primary site’s storage domains. The secondary site’s storage domains must be in read/write mode and the primary site’s storage domains must be in read-only mode.

2. Clean the primary site and remove all inactive storage domains and related virtual machines and templates. For more information, see Section 4.2.5, “Cleaning the Primary Site”.

3. Run the command to failback to the primary site:
4. Enable replication from the primary storage domains to the secondary storage domains.

5. Verify that all relevant storage domains, virtual machines, and templates are registered and running successfully on the primary site.

### 4.2.8 Mapping File Attributes

The attributes in the mapping file are used to failover and failback between the two sites in an active-passive disaster recovery solution.

**Site details**

Attributes that map the Engine details in the primary and secondary site, for example:

```bash
dr_sites_primary_url: https://manager1.mycompany.com/ovirt-engine/api
dr_sites_primary_username: admin@internal
dr_sites_primary_ca_file: /etc/pki/ovirt-engine/ca.pem

# Please fill in the following properties for the secondary site:
dr_sites_secondary_url: https://manager2.mycompany.com/ovirt-engine/api
dr_sites_secondary_username: admin@internal
dr_sites_secondary_ca_file: /etc/pki/ovirt-engine/ca.pem
```

**Storage domain details**

Attributes that map the storage domain details between the primary and secondary site, for example:

```bash
dr_import_storages:
- dr_domain_type: nfs
  dr_primary_name: DATA
  dr_master_domain: True
  dr_wipe_after_delete: False
  dr_backup: False
  dr_critical_space_action_blocker: 5
  dr_warning_low_space: 10
  dr_primary_dc_name: Default
  dr_discard_after_delete: False
  dr_primary_path: /storage/data
  dr_primary_address: 10.64.100.xxx
  # Fill in the empty properties related to the secondary site
  dr_secondary_dc_name: Default
  dr_secondary_path: /storage/data2
  dr_secondary_address:10.64.90.xxx
  dr_secondary_name: DATA
```

**Cluster details**

Attributes that map the cluster names between the primary and secondary site, for example:

```bash
dr_cluster_mappings:
- primary_name: cluster_prod
  secondary_name: cluster_recovery
- primary_name: fc_cluster
  secondary_name: recovery_fc_cluster
```

**Affinity group details**

Attributes that map the affinity groups that virtual machines belong to, for example:

```bash
dr_affinity_group_mappings:
```
Mapping File Attributes

- primary_name: affinity_prod
  secondary_name: affinity_recovery

• Affinity label details

Attributes that map the affinity labels that virtual machines belong to, for example:

```yaml
dr_affinity_label_mappings:
- primary_name: affinity_label_prod
  secondary_name: affinity_label_recovery
```

• Domain authentication, authorization and accounting details

Attributes that map authorization details between the primary and secondary site, for example:

```yaml
dr_domain_mappings:
- primary_name: internal-authz
  secondary_name: recovery-authz
- primary_name: external-authz
  secondary_name: recovery2-authz
```

• Role details

Attributes that provide mapping for specific roles, for example:

```yaml
dr_role_mappings:
- primary_name: admin
  secondary_name: newadmin
```

• Network details

Attributes that map the vNIC details between the primary and secondary site, for example:

```yaml
dr_network_mappings:
- primary_network_name: ovirtmgmt
  primary_profile_name: ovirtmgmt
  primary_profile_id: 0000000a-000a-000a-000a-000000000398
  # Fill in the correlated vnic profile properties in the secondary site for profile 'ovirtmgmt'
- secondary_network_name: ovirtmgmt
  secondary_profile_name: ovirtmgmt
  secondary_profile_id: 0000000a-000a-000a-000a-000000000410
```

If you have multiple networks or multiple data centers then you must use an empty network mapping in the mapping file to ensure that all entities register on the target during failover, for example:

```yaml
dr_network_mappings:
# No mapping should be here
```

• External LUN disk details

LUN attributes allow virtual machines to be registered with the appropriate external LUN disk after failover and failback, for example:

```yaml
dr_lun_mappings:
- primary_logical_unit_id: 460014069b2be431c0fd46c4bdce29b66
  primary_logical_unit_alias: My_Disk
  primary_wipe_after_delete: False
  primary_shareable: False
  primary_logical_unit_description: 2b66
  primary_storage_type: iscsi
  primary_logical_unit_address: 10.35.xx.xxx
  primary_logical_unit_port: 3260
  primary_logical_unit_portal: 1
  primary_logical_unit_target: iqn.2017-12.com.prod.example:444
```
<table>
<thead>
<tr>
<th>Attribute</th>
