Oracle WebLogic Server 12c Administration Handbook
Install, Configure, Manage, and Secure Oracle WebLogic Server 12c

Sam R. Alapati
Oracle ACE
CHAPTER 1

Installing Oracle WebLogic Server 12c and Using the Management Tools
The introduction to this book provided a quick outline of the Java Enterprise Edition (Java EE) and the nature of web applications for which you use Oracle WebLogic Server 12c. Since the primary goal of this book is for you to understand how to administer Oracle WebLogic Server 12c, let’s begin by discussing key administration topics such as installing and upgrading Oracle WebLogic Server and becoming familiar with the administration tools you use day in and day out to manage the server. There are three major administrative tools that are going to be your day-to-day companions when managing Oracle WebLogic Server 12c: the Administration Console, the Node Manager utility, and the WebLogic Scripting Tool (WLST), which is based on the open source Jython language. This chapter briefly introduces these tools, and you’ll learn how to use all three of these tools, as well as other WebLogic Server (this term is used as a synonym for Oracle WebLogic Server 12c throughout the rest of this book) management commands, in later chapters. In this and the next chapter, I make extensive use of the sample Oracle WebLogic Server 12c applications that you can install to learn various administrative and deployment-related concepts. This chapter introduces the Oracle WebLogic Server 12c sample domains that host the sample applications. This and other chapters use the sample domains to explain various Oracle WebLogic Server 12c management concepts. Before we start reviewing the installation, upgrading, and management of Oracle WebLogic Server 12c, however, let’s review the Oracle WebLogic Server 12c product set as well as key terminology and important architectural concepts that illustrate how Oracle WebLogic Server 12c functions.

Oracle WebLogic Server: An Overview

Before you learn how to install, upgrade, and manage Oracle WebLogic Server, let’s quickly review the set of Oracle WebLogic Server 12c products. Following that is a brief summary of key terminology that will help you understand the components of an Oracle WebLogic Server 12c domain, a collection of Oracle WebLogic Server instances and related resources and services that are managed together as a single unit.

Oracle WebLogic Server 12c Product Set

Oracle WebLogic Server 12c is a component of Oracle Fusion Middleware 12c, which consists of several Oracle products that span business intelligence, collaboration tools, content management, and integration services. The underlying application server supporting these middleware applications is Oracle WebLogic Server 12c. Products such as Oracle SOA Suite and Oracle Fusion applications rely on Oracle WebLogic Server 12c to run their code.

Oracle offers three distinct products as part of the Oracle WebLogic Server 12c application family:

- Oracle WebLogic Server Standard Edition (SE)
- Oracle WebLogic Server Enterprise Edition (EE)
- Oracle WebLogic Suite

Oracle WebLogic Server Standard Edition

The Oracle WebLogic Server Standard Edition (SE) is a full-featured application server, targeted for developers to aid in getting enterprise applications up and running quickly. Oracle WebLogic Server SE implements all the Java EE standards and offers management capabilities through the Administration Console.
Oracle WebLogic Server Enterprise Edition

Oracle WebLogic Server EE is the core application server designed for mission-critical applications that require high availability and advanced diagnostic capabilities. The EE version contains all the features of the SE version, of course, but in addition supports clustering of servers for high availability and the ability to manage multiple domains, plus various diagnostic tools.

Oracle WebLogic Suite

Oracle WebLogic Suite integrates the core WebLogic Server application server within the Oracle WebLogic Suite Java Infrastructure. The Oracle WebLogic Suite offers support for dynamic scale-out applications with features such as in-memory data grid technology and comprehensive management capabilities. It consists of the following components:

- Oracle WebLogic Server EE
- Oracle Coherence (provides in-memory caching)
- Oracle Top Link (provides persistence functionality)

This book deals exclusively with the Oracle WebLogic Server EE 12c product. (I refer to it simply as WebLogic Server in the rest of the book.) You manage WebLogic Server essentially the same way regardless of the operating system it is running on. This book uses examples run on a Windows installation of WebLogic Server; however, where necessary or relevant, certain tasks or commands are also shown for UNIX/Linux-based systems.

NOTE

WebLogic Server uses a configured pool of JDBC connections to interact with databases. You can use any RDBMS that supports a JDBC 2.0–compliant driver. This includes Oracle, IBM DB2, Microsoft SQL Server, MySQL, and other databases. The WebLogic Server installation includes an embedded database called Apache Derby. (Previously, Oracle shipped a different database by the name of PointBase.)

Terminology

Before we delve into the administration of WebLogic Server, I want to make sure you clearly understand the key terminology you’re going to encounter throughout the book. Some of the WebLogic Server terms and definitions are obvious, but others aren’t, such as the concept of a machine, for example.

WebLogic Server Instance

A WebLogic Server instance is a Java Virtual Machine (JVM) process that runs the Java code. The instance is the actively working component, receiving client requests and sending them on to the appropriate components, and sending the processed requests back to the originating clients. The server instance manages the resources necessary for applications, such as the JTA and JDBC services, to function. In each domain (to be explained in the following section), one instance serves as the Administration Server, which is your primary means of managing the domain. The rest of the WebLogic Server instances in a domain are called Managed Servers. If you have a domain with just one WebLogic Server instance, as in the case in a development environment, the single server instance functions as both the Administration Server and the Managed Server. Note that the terms WebLogic Server and WebLogic instance are often used interchangeably.
WebLogic Server Domain

A **domain** is a set of WebLogic Server instances (managed servers) that you manage with the Administration Server, which itself is nothing but another WebLogic Server instance, albeit a special one. Any configuration changes you make to a domain will apply to all members of that domain. Domains offer you ease of administration—for example, you can apply configuration changes on a domain-wide basis that apply to all the management servers that belong to that domain. Every domain has exactly one Administration Server, which is used to configure and manage that domain. In addition to the WebLogic Server instances, a domain also includes the application components that you deploy, as well as all the services required by the server instances of that domain. The Administration Server is usually referred to as the Admin Server for short.

A domain offers you the administrative ease you need to manage your WebLogic environment. A domain encompasses the Admin Server, Managed Servers (including those configured into WebLogic clusters), machines (servers), and all the services necessary to run your applications. The fact that a domain includes all the configuration data for the servers, deployments, and the physical network makes it easy to configure and manage complex, geographically dispersed WebLogic Server deployments. A domain lets you simultaneously deploy applications across multiple WebLogic Server instances located on heterogeneous servers and various networks, with different physical and network descriptions. Administering a domain makes it possible for you to configure high availability with the help of multiple WebLogic Server instances and administer various services spread across heterogeneous host servers.

The first step in using Oracle WebLogic Server to deploy applications is to create a domain. As mentioned earlier, a domain can just consist of a single Admin Server, with no Managed Servers at all, as is common in a development environment. A production cluster ranges over several physical machines to provide high availability and failover protection, but you can also configure a cluster on a single server for testing and development purposes. WebLogic Server stores the configuration information for a domain in the `config.xml` file, which is stored on the machine where the Admin Server runs and serves as the domain's configuration file. The domain also contains security settings, log files, and startup scripts for the Admin and Managed Servers that belong to that domain. The WebLogic Configuration Wizard and the WebLogic Domain Wizard offer you extremely easy ways to create domains, as well as the servers and clusters that belong to that domain.

**NOTE**

Each Managed Server contains a local copy of its domain configuration. Upon startup, it synchronizes its configuration with the Admin Server. Similarly, when you make domain configuration changes on the Admin Server, those changes are propagated to the Managed Server's configuration.

Administration Server

A **server** is an instance of WebLogic Server that runs in its own JVM, and the Administration (or Admin) Server is a special instance of WebLogic Server designed for managing the domain rather than running applications. There is a one-to-one relationship between domains and the Admin Server—an Admin Server belonging to Domain A can't manage Domain B.

You can deploy applications on the Admin Server, but unless you’re operating in a purely developmental environment, use the Admin Server strictly for performing management tasks, not for deploying any applications. Although you can deploy applications on the Admin Server in a
development environment, it’s a best practice not to do so in a production environment. For one thing, you don’t want application work to compete with administrative work in a production environment. You also want to firewall the Admin Server separately so external clients can’t access it.

The Admin Server is critical to the functioning of a WebLogic Server domain because it manages the domain configuration, including the servers that are part of the domain, as well as all the applications and services you deploy to the various servers. Apart from this management of the domain configuration information, the Admin Server has all of the functionality of a Managed Server; in fact, an Admin Server runs the same code and is managed internally the same way as a Managed Server. The Admin Server hosts the Administration Console, which is a web application front end used for configuring, monitoring, and managing a domain. You can access the Administration Console with any supported browser that can access the Admin Server. All WebLogic system administration tools and APIs interact with the Admin Server. If you install the optional Node Manager service, the Admin Server communicates with the Node Manager service on each machine to talk to the Managed Servers running on that machine.

**Managed Server**

Managed Servers are the workhorses of WebLogic Server. Any additional servers you create after the creation of the default Admin Server are Managed Servers. The Managed Server contacts the Admin Server upon startup, to get its configuration and deployment settings. For this reason, you should always start the Admin Server before you start a Managed Server. Once a Managed Server starts running, it operates completely independently from the Admin Server.

Although you can deploy a Java EE application to the Admin Server itself, the recommended approach is to deploy applications to the Managed Servers. In a production environment, it’s common to run multiple Managed Servers as part of a cluster. A Managed Server hosts your Java EE applications, as well as all related resources and services such as Java Database Connectivity (JDBC) connection pools and data sources, Java Transaction API (JTA) transaction services, and Java Messaging Service (JMS) connection factories that are necessary to support application deployments. On startup, a Managed Server contacts the Admin Server to retrieve any configuration changes since the Managed Server was last shut down. A Managed Server can continue to run, however, and it’s even possible to start it in the absence of an Admin Server. Chapter 2 shows how you can start a Managed Server without a running Admin Server, in the special Managed Server Independence (MSI) mode. The MSI mode is enabled by default, and it allows the Managed Server to start using its locally cached configuration without having to contact the Admin Server for this information.

**WebLogic Server Cluster**

A WebLogic Server cluster is a group of WebLogic Server instances consisting of multiple Managed Servers that run simultaneously. The multiple Managed Servers work together to provide replication services for one another, and the Admin Server isn’t generally a part of any cluster. Most production deployments use clusters to increase reliability and scalability through load distribution and high availability. To achieve the high availability capability, you deploy resources and services in a homogeneous fashion on each of the Managed Servers that are part of a cluster. Clusters host applications that respond to HTTP requests that are routed to the cluster through a hardware load balancer. You can also set up load balancing on a WebLogic Server instance or a third-party web server with the help of plug-ins supplied by WebLogic Server. The load balancer handles the HTTP requests after the requests pass through a firewall. Cluster members pass replicated copies of objects such as HTTP sessions among themselves to provide the failover capability for the cluster.
NOTE
The simplest domain will consist of just one server—the Admin Server. In a development environment, you can sometimes get by with such a simple setup and host all applications directly on the Admin Server without using a Managed Server or a cluster comprising several Managed Servers.

A WebLogic Server domain can consist of multiple Managed Servers that either are or are not part of a cluster, or it can consist of multiple clusters—just remember that even if you have multiple Managed Servers in a domain, you can avail yourself of WebLogic Server’s high availability and load-balancing features only by deploying a cluster of servers. High availability lets you continue serving clients even when you experience a failure, such as a machine or WebLogic Server failure. WebLogic Server offers you many powerful features, including replication, failover, and the ability to migrate services so you have high availability for your system. Clusters provide load-balancing capabilities by letting you spread requests across the cluster members. Clusters also offer scalability by letting you easily add additional servers to the cluster to accommodate increased demand for WebLogic Server services. The important thing to understand here is that the cluster automatically provides these capabilities, so your users won’t have to experience service disruptions. Each WebLogic domain may consist of multiple Java EE resources, such as JDBC connection pools and JMS servers, which the domain makes available to all the applications it hosts. Note that domain resources, like a JDBC connection pool, aren’t shared across domains—each WebLogic domain must create its own set of resources. This requirement applies when dealing with clusters as well, which are treated as domain resources. A cluster’s Managed Servers thus can’t overlap domains and belong to more than one domain at the same time. Therefore, whenever you perform a failover within a cluster, you can fail over from one Managed Server to another Managed Server within the same domain but not to a Managed Server that belongs to a different domain.

How does one design a domain? Once you satisfy the simple requirement that you must install the same version of WebLogic Server for all the Managed Server instances in a cluster, it’s easy to design a cluster. Although a WebLogic Server cluster can run entirely on a single machine, to take advantage of the high availability features, a cluster’s member servers are typically installed on two or more physical machines. To increase a cluster’s capacity, you can either add more Managed Server instances to the existing cluster architecture, or you can add more physical machines to the cluster, with the additional machines hosting new Managed Server instances, of course. Managed Servers can serve as backups for services such as JTA and JMS that another Managed Server in the same cluster hosts.

Coherence Cluster
A domain may also include Coherence Clusters, which are groups of cluster nodes that share a group address to facilitate communication among the nodes. In addition, a WebLogic Server domain may also include a Managed Coherence Cluster, which is any WebLogic Managed Server assigned to a Coherence Cluster.
Machine

A machine in the WebLogic Server context is the logical representation of the computer that hosts one or more WebLogic Server instances (servers). The Admin Server uses the machine definitions that you create to start remote servers through the Node Managers that run on those servers. A machine could be a physical or virtual server that hosts an Admin or Managed Server that belongs to a domain. You’ll see later in the book that you must define a machine first if you want the Admin Server to use the Node Manager service to monitor, start, and stop the Managed Servers running on a server. In a sense, a machine in a WebLogic Server environment is more or less equivalent to an instance of a Node Manager, and this is essentially the concept that a machine represents. WebLogic clusters make use of the machines you define in order to decide the optimal way to replicate session data on a different server that is part of a cluster.

Network Channels

Network channels are an optional feature that allows you to separate different classes of network traffic. You can make use of separate network channels to separate server and client traffic and direct it to different listening ports or addresses. If you need to allow both secure and nonsecure traffic on the same server, you can create multiple channels to support the diverse traffic with different security protocols. You can also use network channels to manage quality of service by using weighted, value-based priorities for different channels. This enables you to assign high-weighted values to faster channels that use faster network interface cards and dedicate them to the types of traffic that require faster throughput, for example. Network channels control all communication-related aspects such as listen addresses, protocols, and port numbers throughout the domain.

Node Manager

The Node Manager is an optional process that runs on a machine and manages the availability of all servers that run on that machine. Node Managers help you remotely start, stop, suspend, and restart Managed Servers. The Node Manager works with the Admin Server using a secure channel and lets you manage the availability, as well as monitor the health, of all Managed Servers in a single domain. The Managed Servers that the Node Manager controls can be independent servers or they can be members of a cluster. The Node Manager monitors remote Managed Servers and is capable of automatically restarting them when they fail. It also kills Managed Servers that exhibit unstable behavior. It is recommended that you install a Node Manager service on each machine that hosts a Managed Server. Managing the servers with Node Manager is actually a key requirement for configuring automatic server migration in a cluster following a server failure, as explained in Chapter 7. In Chapter 2, I explain how you can use Node Manager and the WebLogic Scripting Tool (WLST) together to perform various administrative tasks.

Virtual Host

A virtual host relies on the Domain Name System (DNS) to map hostnames to the IP address of a single server or a cluster of servers. By doing so, multiple domain names can be hosted on your server wherein different web applications can be assigned to different virtual hosts, effectively sharing all resources and being differentiated only by their hostnames.

Work Manager

A Work Manager helps you manage the WebLogic Server instance workload, specifically by letting you prioritize work execution, which you do by defining request classes and constraints. You can configure a Work Manager at the domain level (using a global Work Manager) or at the application or module level.
Services
Following are some of the main services used in a WebLogic environment:

- JDBC (Java Database Connectivity) enables Java programs to handle database connections established through connection pools.
- JMS (Java Messaging Service) is a standard API that enables applications to communicate through enterprise messaging systems.
- JTA (Java Transaction API) specifies standard Java interfaces between transaction managers and the parties in a distributed transaction system.

TIP
You can create Jolt Connection Pools to enable your applications to connect to Oracle Tuxedo domains. Jolt clients will then manage requests from your applications to the Oracle Tuxedo Services.

Deployment
When you want to make a Java EE application or a stand-alone application module available to users, you must first install those applications and modules in a WebLogic domain. Once you install the applications and modules, you must start those so the applications can begin processing user requests. Deployment is the process of installing the applications or modules and starting them so they are available to clients. Developers package applications for delivery to administrators, who then deploy the applications to WebLogic Server instances or clusters. Chapter 8 shows the various ways in which you can deploy applications to development and production environments by using the Administration Console, WLST, and the `weblogic.Deployer` utility.

NOTE
Oracle WebLogic Server 12c fully supports Oracle Real Application Clusters (RAC). Chapter 4 shows you how to configure data sources to connect to Oracle RAC database services.

Security Realm
You use security realms to protect WebLogic Server resources. A security realm is simply a logical container for your users, groups, roles, security policies, and security providers. It’s the security realm that authenticates users and determines which resources they can access. WebLogic Server uses a default security realm named `myrealm`. In the default security realm, the Admin Server stores the domain security data in an LDAP server, but you can also choose an RDBMS store for this instead. The Managed Servers replicate this LDAP server, and when the Admin Server fails, it can use their copy of the LDAP server for providing security services to the deployed applications.

When you create a domain, the username/password credentials you provide are used by the Configuration Wizard to seed the security realm `myrealm`. The username you provide will be the initial administrative user in `myrealm`. When you start WebLogic Server, it uses the default security realm to authenticate usernames. You can configure the server to use other security realms, but you must always specify one of them as the default security realm.

If these simple definitions of the key WebLogic Server terminology don’t satisfy your curiosity, not to worry—subsequent chapters discuss all these entities in great detail!
Important WebLogic Server Concepts

In order to fully comprehend how WebLogic Server works and to get the best performance out of it, it’s important to understand several concepts. The most significant concepts are discussed in the following section.

Execute Threads and Queues

Understanding the internal architecture of Oracle WebLogic Server is important, particularly in terms of knowing how the server performs its work of satisfying user requests. When a client sends a request to WebLogic Server, the actual work to satisfy that request is performed by a Java thread called an execute thread. A user can submit work to WebLogic Server using an HTTP-based request to the servlet engine or a request for Remote Method Invocation (RMI) access to objects such as Enterprise JavaBeans (EJBs). When a server process starts, it binds itself to a port and assigns a listen thread to the port to listen for incoming requests. Once the request makes a connection, the server passes control of that connection to the socket muxer. The socket muxer reads requests off the socket and places the work requests into the self-tuning execute queue as they arrive. An idle execute thread will pick up a request from the execute queue and may, in turn, hand off the job of responding to those requests to special threads. The execute thread executes the requests and returns the responses.

Oracle WebLogic Server uses socket muxers, which are software modules, to read incoming requests on the server. Muxers read messages from the network, bundle them into a package of work, and queue them to the Work Manager, which then finds a thread on which to execute the work and makes sure the response gets back to the same socket from which the request came. There are two types of muxers—a Java muxer and a native muxer. A Java muxer uses pure Java to read data from the sockets, whereas the native muxers use platform-specific native binaries. By default, Oracle WebLogic Server uses the native muxer. This means that the Enable Native IOP parameter for the server is set to the value SELECTED. Note that with a native muxer, the server creates a fixed number of threads to read incoming requests, whereas with a Java muxer you can configure the number of threads in the Administration Console by modifying the Percent Socket Readers parameter. The native muxer allocates a certain percentage of the server threads to act as socket reader threads, which perform the pooling function, while the rest of the server threads are busy processing client requests. In general, you need to be careful about changing the number of socket reader threads. In many cases, the best optimization is to set it to 1.

You can tell if you’re using a native muxer or a Java muxer by looking at the messages that involve the execute thread. If you’re using the native muxer, the server error messages will refer to it as weblogic.socket.EPollSocketMuxer, whereas if you’re using the Java muxer, you’ll see weblogic.socket.SocketMuxer instead. Note that the EPollSocketMuxer is associated only with a JRockit JVM operating on a Linux server. You’ll see the word poll in the case of a native muxer because it uses a polling mechanism to query a socket for data. Native muxers are seen as providing superior performance, especially when scaling up to large user bases, because they implement a nonblocking thread model. When administering WebLogic Server instances, you’ll frequently encounter the so-called stuck thread situation, which occurs when a thread isn’t returned to the thread pool within the timeframe you set for it (the default is 10 minutes). Resolution of stuck threads is a key component of WebLogic Server troubleshooting, and you’ll notice that Oracle Support often asks for several server thread dumps when you open a service request. Chapter 6 shows you how to take a thread dump and analyze many performance issues on your own by identifying the resource contention leading to the stuck thread situation.
Implementing the JMX API and MBeans

WebLogic Server implements the system administration infrastructure with Oracle's Java Management Extensions (JMX). Implementing the JMX API involves using Java MBeans (managed beans) to model system administration tasks. If you understand MBeans and the JMX API, you can use them to create your own custom management tools. However, all administrative tools, such as the Administration Console, use the same MBeans and JMX API, so you don’t have to reinvent the wheel by creating custom management tools. Although a WebLogic Server administrator doesn’t need to know how to program the JMX API, it helps to understand the different types of MBeans and how the JMX API interacts with them.

WebLogic Server uses two basic types of MBeans—configuration MBeans and runtime MBeans—to configure, monitor, and manage the server and its resources.

- **Configuration MBeans** contain the configuration information for servers and resources that is stored in the domain’s configuration files such as the config.xml file and other XML files. These are persistent MBeans, and the domain’s configuration file, config.xml, stores the attribute values for these MBeans. Whenever you change a configuration attribute using a system administration tool such as the Admin Server, those changes persist in the config.xml file. Configuration values can also be set by modifying the startup scripts and adding additional arguments via the -D option in the Java startup command. The config.xml file automatically gets updated when you change any configuration settings. When a Managed Server starts, it contacts the Admin Server and gets a copy of the configuration details, which it stores in memory as configuration MBeans. Thus, all server instances in a domain have the same in-memory representation of the domain’s configuration. Note that any attributes you change when starting a Managed Server won’t affect the config.xml file, which is modified only if you change an attribute value on the Admin Server. When you shut down a server instance, all configuration MBeans hosted by that server are destroyed.

- **Runtime MBeans** help you monitor running server instances and contain attributes that hold run-time information for server instances and applications. Each of the server’s resources updates the relevant runtime MBean following a change in its state. For example, the ServerRuntimeMBean is instantiated by the server when it starts and contains the run-time data for the server. Runtime MBeans consist only of run-time data and nothing else, and when you shut down the server, the run-time statistics in the ServerRuntimeMBean are destroyed, as is the case with all the other runtime MBeans.

MBean Servers act as containers for the various MBeans, and the servers create and provide access to the MBeans. Oracle provides three types of MBean Servers. The Admin Server hosts an instance of the Domain Runtime MBean Server, which manages the MBeans for domain-wide services. Both Managed Servers and the Admin Server host an instance of the Runtime MBean Server, which lets you configure server instances. The Admin Server also hosts the Edit MBean Server, which manages pending configuration changes. The Admin and the Managed Servers also can optionally host the JVM’s Platform MBean Server, which controls MBeans that contain monitoring information for the JDK.

You can change most domain configuration attributes dynamically while the server instances are running. In cases where dynamic configuration of an attribute isn’t possible, you must restart the server instance. Run-time values of the attributes you configure will reflect your changes immediately, and the values are persisted in the config.xml file.
Development and Production Mode

By default, WebLogic Server domains run in development mode using Oracle’s Java Development Kit (JDK). In this mode, auto-deployment of applications is enabled and the Admin Server creates a `boot.properties` file automatically when you start it. You can also use the demo certificates for Secure Sockets Layer (SSL) without any warnings from WebLogic Server. The development mode is provided to get developers up and running quickly without having to worry about advanced deployment, configuration, or security issues.

In production mode, WebLogic Server defaults to using JRockit as the default JDK. In addition, you can’t use the auto-deployment feature in production, and WebLogic Server issues warnings if you use the demo certificates for SSL. In production mode, you’re also prompted for usernames and password when you start the instances.

It’s easy to toggle between development and production modes, and you learn how to in Chapter 2.

Listen Ports and Listen Threads

Listen ports listen for connection requests, and, as connections come in, the listen thread assigned by the server to the listen port accepts the connection requests, establishes connections, and hands the requests over to the socket muxer.

By default, Oracle WebLogic Server uses two listen ports to listen to incoming requests for connections. The first listen port, which I’ll call a `normal listen port`, accepts any type of request—administrative as well as user requests. The normal listen port accepts connections from various protocols such as HTTP, t3, IIOP, COM, LDAP, and SNMP. When you start a WebLogic Server instance, it starts listening on two different ports. The first one is a normal plaintext port, and the second is an SSL listen port that also accepts requests for connections from clients over protocols such as HTTPS, t3s, IIOPS, COMS, and LDAPS.

The second listen port is called an `administration port`. When you configure an administration port, the requests must use SSL, at which point you won’t be able to direct any administrative requests to the normal port. Here’s an informational message from the server when it starts. The message shows the two default listen ports in action:

```
May 25, 2013 11:05:23 AM CDT <Notice> <Server> <BEA-002613> <Channel
"Default" is now listening on 192.168.123.113:7001
for protocols iiop, t3, ldap, snmp,http.>
```

```
May 25, 2013 11:05:23 AM CDT <Notice> <Server> <BEA-002613> <Channel
"DefaultSecure[3]" is now listening on 192.168.232.1:7002 for protocols iiops,
t3s, ldaps, https.>
```

Although using the administration port is optional, note that you can start a server in the standby mode only if you use an administration port. In standby mode, the normal port will be unavailable, so you must use the administration port to manage the server. In addition, having two separate ports—one for administrative operations and the other for the application traffic—prevents a conflict between these two types of network traffic. In a production environment, you can thus ensure that critical administrative operations, such as starting and stopping servers or deploying applications, don’t compete with the application traffic. The administration port accepts only secure SSL traffic, so all connections through this port will have to be authenticated. Note that only administrative users can authenticate on the administration port, and no administrative traffic is rejected on non-admin ports when you enable the administration port.
Choosing a JVM
To run Oracle WebLogic Server, you need a Java Virtual Machine (JVM). Oracle offers two types of JVMs for you when you install Oracle WebLogic Server—the Sun HotSpot JVM and the Oracle JRockit JVM. Oracle recommends that you use the JRockit JVM for production installations because of the many benefits it offers, including higher performance, increased scalability, and better manageability when compared to the Sun HotSpot JVM.

You configure the default JVM for a domain when creating a domain with the Configuration Wizard or with the WebLogic Scripting Tool (WLST). Of course, you can reconfigure the choice of a default JVM later on as well. If you choose Production Mode on the Configure Server Start Mode and JDK page during the Configuration Wizard's domain creation process, the choice of the JVM will default to the JRockit SDK. If you select Development Mode, on the other hand, your domain will be configured to use the Sun HotSpot SDK.

Changing the JVM after you create the domain is easy. Just set the JAVA_VENDOR environment variable in the startWebLogic.cmd script (or the startWebLogic.sh script in UNIX), as shown here:

```
$ set JAVA_VENDOR=BEA              /* For JRockit JVM
$ set JAVA_VENDOR=oracle                  /* for Oracle JVM
```

You can also set the value of the JAVA_VENDOR variable to Oracle in order to specify the JRockit JVM. You can confirm the JVM version the server is using by viewing the command window output after you start a WebLogic Server instance. Be sure to check the JRockit documentation for vendor-specific options if you’re new to this JVM. You can use JRockit to run any applications that were created with the Sun HotSpot JDK.

Using Web Server Plug-Ins
Although WebLogic Server comes with a built-in web server, you can also use a third-party web server, such as the Apache HTTP Server, for example. Web servers can be used to field requests for simple, static HTML content; but dynamic content, such as that delivered by Java web applications developed as JSPs or servlets, are hosted on the WebLogic Server and the web server routes requests for the dynamic content to WebLogic Server. The web server can use a WebLogic proxy plug-in or the WebLogic Server–provided servlet named HTTPClusterServlet to direct servlet and JSP requests to the cluster. You must configure HTTPClusterServlet as the default web application on the proxy server machine if you want to use this instead of a proxy plug-in.

You can install a WebLogic plug-in on the web server, allowing it to talk to the applications running on WebLogic Server. Your WebLogic Server installation comes with plug-ins for the following web servers:

- Apache HTTP Server
- Microsoft Internet Information Server
- Oracle Java System Web Server

You can use a proxy plug-in to proxy requests from the web server to the clustered WebLogic Server instances to provide load-balancing and failover capabilities for those requests. You can configure the Secure Sockets Layer (SSL) protocol to secure data exchanged between the Apache HTTP Server Plug-In and WebLogic Server. Please refer to the Oracle WebLogic Server documentation on WebLogic Server plug-ins for more details about the various available plug-ins.

Although you can use WebLogic Server for its capabilities in hosting dynamic enterprise-level applications, you can also use it as a full-fledged web server capable of hosting high-volume web sites and server-static HTML files, servlets, and JSPs.
Management APIs

All the WebLogic Server administration tools and utilities you’ll use to manage WebLogic Server call on various WebLogic application programming interfaces (APIs) to perform their tasks. Instead of relying exclusively on the management tools, you can also make use of the rich offering of WebLogic APIs to create your own custom management utilities. Here are brief descriptions of the key management APIs:

- **WebLogic Diagnostic Service APIs**  These APIs support monitoring of the servers and the access and control of diagnostic data.

- **Java Management Extensions (JMX)**  JMX is a public standard that you can use for monitoring and managing applications, devices, system objects, and service-oriented networks. WebLogic Server uses JMX-based services to manage its resources.

- **Deployment API**  The deployment API enables the configuration and deployment of applications.

- **Logging APIs**  Logging APIs help you write messages to log files and distribute those messages. WebLogic Server offers both the standard JDK logging APIs as well as the Jakarta-Log4J Project APIs.

- **Java EE Management API**  This API enables you to create tools to discover resources such as connection pools and deployed applications.

Here are some things to note about the various management APIs:

- They implement and usually extend the relevant Java specification. For example, the deployment API implements the JSR-88 deployment specification.

- They enable you to integrate management tasks with other tools that comply with the same specification.

- The WebLogic Server administration tools, such as the Administration Console, use these APIs to perform various management tasks.

Installing Oracle WebLogic Server 12c

This section shows you how to install the latest release of WebLogic Server. As you’ll see, the installation is remarkably easy. Of course, once you create your WebLogic Server domain, you’ll need to configure it, and this could take a significant amount of time. Chapter 3 explains WebLogic Server domain configuration.

Although the installation steps and screenshots pertain to a Windows installation, they’re similar to the installation steps you need to follow for a UNIX or Linux installation, except for a few operating system differences. All the scripts provided for starting and stopping the servers, for example, come in two versions—a Windows and a UNIX version. So the counterpart in UNIX for the Java Windows command script for starting a Managed Server, `startManagedWebLogic.cmd`, is the `startManagedWebLogic.sh` script.

**NOTE**

You can download the WebLogic Server installation files from the Oracle E-Delivery web site (http://edelivery.oracle.com) or from the Oracle Technology Network (OTN) web site.
Oracle offers Oracle WebLogic Server zip distribution, as in previous releases for development use, both for Windows and Linux (and Mac OS X) platforms. The zip distribution is intended purely for WebLogic Server development, and you must not use this in production environments. You can download both the generic installers and the zip distribution from the Oracle Technology Network site. Neither the generic installer nor the zip distribution includes a JVM/JDK. You can download installers with just Oracle WebLogic Server or one with Oracle Coherence and Oracle Enterprise Pack for Eclipse as well. Although it has a smaller footprint than the full-deployment version, note that the development-only installation doesn’t come with the web server plug-ins, the Sun HotSpot or JRockit JDK, the sample applications, or the Derby database.

You can choose one of the following two generic self-extracting installer JARs for installing Oracle WebLogic Server 12c on any platform:

- **wls_121200.jar**  Installs WebLogic Server and Coherence
- **fmw_infra_121200.jar**  Installs WebLogic Server, Coherence, and infrastructure components for Fusion Middleware product platforms.

Let’s turn to how you install Oracle WebLogic Server on a Windows system.

### Installation Prerequisites

The installation procedures explained here are for the Windows platform, and they’re mainly designed to get a working installation of WebLogic Server up and running so you can play with it. For example, the prerequisites for a basic installation require just 1GB of RAM and a 1 GHz processor. As for disk space for the installation, it takes about 2GB for the entire installation (including Oracle Coherence and Oracle Enterprise Pack for Eclipse). For actual production implementations, you must refer to the appropriate requirements.

A key requirement is that you must have a Java Development Kit (JDK) installed prior to the installation.

### Installation Modes

There’s more than one way to install WebLogic Server. The first and easiest method is to use the graphical mode, which is an interactive mode. The console mode is also an interactive mode, but it is run from the command line. The silent mode is a noninteractive mode of installation, where you can use a script or a text file when you need to install WebLogic Server on many hosts. The example that follows uses the graphical mode to install WebLogic Server.

In most operating systems, the installer will also automatically install the Java run-time JDKs. The two types of JDKs available are the Sun HotSpot JDK and the Oracle JRockit JDK. Oracle recommends that you use the JRockit JDK in production environments.

In this book, the installer used is named **wls_121200.jar**. Unlike in the previous release, WebLogic Server 12c doesn’t include a JDK. Make sure you already have a JDK or download one from Oracle before you start the installation. You must do the following before you start the installation of WebLogic Server:

1. Install the JDK.
2. Set the `JAVA_HOME` variable to the path of the JDK you’ve installed.
3. Update the `PATH` environment variable to include both the `JAVA_HOME` and the `JAVA_HOME/bin` directories.
Installation Procedure
Follow these steps to install WebLogic Server:

1. Execute the following command to extract the jar file you’ve downloaded from the Oracle site and to launch the Oracle Fusion Middleware 12c Installer:

   ```
   C:\Program Files\Java\jdk1.7.0_40\bin>java -jar c:\downloads\wls_121200.jar
   Extracting files............................................
   ```

2. On the Welcome screen, click Next to proceed with the installation.

3. The Installation Location Screen lets you enter the location where you want to install WebLogic Server. In this example, the location is C:\Oracle\Middleware. Click Next.

4. On the Installation Type screen, you have three choices: the WebLogic Server Installation, Coherence Installation, and Complete Installation. Select Complete Installation, as shown here. Note that this also includes the Server Examples, which contain several sample WebLogic Server domains that help you learn more about WebLogic Server application development and deployment. In a production environment, do not install the Server Examples, of course! Click Next.

5. The Installation Summary shows all the products and features that will be installed. Click Install once you review the product and feature list.
6. The Prerequisite Checks page shows the status of the operating system certification check and the checking of the Java version used to run the installer. Once these two checks are successful, click Next.

7. You’ll see the Installation Progress screen next, marking the progress of the installation. When this screen shows 100% completed, as shown here, click Next.

8. On the Installation Completed screen, you’ll see the following message at the bottom of the screen:

   *Oracle WebLogic Installation Completed Successfully.*

   Click Finish.

   Because you chose to install the WebLogic Server Examples (by selecting the Complete Installation option), you’ll see an option on the Installation Complete screen to Automatically Launch The Quick Start Configuration Wizard to configure the WebLogic Server sample domains. This option is already prechecked, so you don’t need to do anything if you want the sample domains to be created in the newly installed WebLogic Server installation. In a production environment, you must uncheck the option to create the sample domains.
Chapter 1: Installing Oracle WebLogic Server 12c and Using the Management Tools

For the sample domains, the SSL, Coherence, and Coherence Storage options are preconfigured and enabled by default and you can’t change them. You must, however, specify the following settings for the sample domains:

- Administrative Server username/password
- Domain and application parent directories
- Listen port and listen address for the Administration Server
- SSL listen port and the Coherence listen port (if applicable)

Once the Quick Start Configuration Wizard starts, enter a password for the WebLogic Server on the first screen (shown here) and click Create.

The Configuration Progress screen that displays next indicates that three example domains—wl_server, medrec, and medrec-spring—are generated by the Quick Start Configuration Wizard. Click Next.

The Configuration Success page shows the domain and application home information and the status for our three sample domains. Once you confirm that the status shows Successful for all three sample domains, click Finish. The following illustration shows the Configuration Details, indicating that all three of the sample domains have been successfully created. It also provides domain and admin location and the connection URL to the Administration Server for each of the three domains (remember that each WebLogic Server has its own separate Administration Server).
If you don’t use the Quick Start Configuration Wizard by launching it from the installer, you must run the Configuration Wizard (or WLST) later on to configure the WebLogic sample domains. If you do this, you must also edit the EXAMPLES_HOME\wl_server\examples\src\examples.properties file to set the administrator credentials for the sample domains.

The installation of Oracle WebLogic Server 12c is complete at this point. It was easy, wasn’t it?

Checking the Installed Features
Once the installation is completed, the installer places the WebLogic Server icons in the Windows Start program. Go to Oracle | Oracle Home | WebLogic Server 12c (12.1.2) for Eclipse | Oracle WebLogic, where you’ll find the newly installed WebLogic Server program components under Oracle WebLogic. Click WebLogic Server 12c to explore the installed products, which are summarized next.

Online Documentation
This is a link to the Oracle WebLogic Server 12c documentation, so you have the relevant Oracle manuals at your fingertips.

Uninstall Oracle WebLogic
The Uninstall Oracle WebLogic option lets you access the Oracle Uninstaller to remove an existing WebLogic Server installation easily. The Uninstaller removes the entire WebLogic Server Platform installation with just a single click. On a Windows system, for example, the Uninstaller removes all files, shortcuts, Windows registry keys, and registry entries related to WebLogic Server.
Tools Under Tools, you’ll find several important wizards. The Configuration Wizard helps you create a domain or modify and extend an existing domain. The Domain Template Builder helps you create domain templates that you can use with the Configuration Wizard to easily create new domains. A domain template provides preconfigured settings that include database components, services and security, and other environmental options. The Domain Template Builder also helps you create extension templates that you can use with the Configuration Wizard to update WebLogic domains. The new Reconfiguration Wizard helps you update an existing WebLogic Server installation to a new release. Finally, you can use the WebLogic Scripting Tool shortcut to start WLST; I discuss how to use WLST toward the end of this chapter, in the section titled “Using the WebLogic Scripting Tool (WLST).”

Reinstalling WebLogic Server
If you need to reinstall an identical version of WebLogic Server in the same location as a previously existing installation for any reason, first remove the previous installation by clicking the Uninstall Oracle Middleware shortcut under Start | Oracle| Oracle Home. This invokes the Oracle Uninstaller wizard, which leads you through the necessary steps to remove an installation. Make sure you stop all running WebLogic Server instances before you start uninstalling.

You can also manually start the deinstaller by going to the ORACLE_HOME/oui/bin directory and issuing the following command:

$ deinstall.cmd

Once the deinstaller completes its work, you must manually remove the ORACLE_HOME directory where you installed Oracle WebLogic Server. You can add new products to an existing installation, but you can’t reinstall the same WebLogic Server release over an existing WebLogic Server installation of the same release.

Exploring the Installation Directories
Now that you’ve seen how easy it is to install WebLogic Server, let’s explore the installation directories a bit. As I mentioned during the installation steps, you have two major home directories—Oracle Middleware Home and Oracle WebLogic Server Home. The Oracle Middleware Home directory is where all the WebLogic Server and other middleware product files are located—it’s the top-level directory for all Oracle Fusion Middleware products, including the Oracle WebLogic Server. In this example here, there’s only a single middleware product, which, of course, is Oracle WebLogic Server. During the installation, I chose C:\Oracle\Middleware as the Oracle Middleware Home directory, denoted by MW_HOME. WebLogic Server creates a directory called Oracle_Home under C:\Oracle\Middleware to serve as the Oracle Home directory. Remember, however, that, by default, the Oracle Installer installs WebLogic Server under the Middleware Home directory, but you are not required to install it here—you can choose to create the Oracle Home in any directory you choose, including a brand new directory for which you need only provide the name. The Installer will automatically create that directory for you. If you’ve installed and removed WebLogic Server earlier, Oracle recommends that you reuse the same directory for your new installation.

Table 1-1 shows the main directories under the Oracle_Home directory. Note that the last directory in the table is your WebLogic Server Home directory and that it’s usually denoted by the environment variable WL_HOME.
Let’s review what’s been accomplished thus far: Following along with this example, you’ve successfully installed the Oracle WebLogic Server software, located in its Home directory, C:\Oracle\Middleware\wlserver_12.1. You don’t have a custom domain yet, however, because you have to create it. The new server does include the three Oracle WebLogic Server sample domains because you chose to have the Installer create them during the server installation. You can’t do a whole lot with this installation in terms of deploying applications and so on, until you create your own WebLogic Server domain. When you create a domain, you’ll automatically have one Admin Server, and you can also create multiple Managed Servers or clusters to host your web applications. Chapter 3 is devoted to managing and configuring domains. In that chapter, you learn how to create domains and configure servers so you can get ready to deploy and run your web applications through Oracle WebLogic Server.

**WebLogic Server Home**

The WebLogic Server Home directory is simply the directory where we installed WebLogic Server, and, by default, it’s located in the MW_HOME\wlserver directory. You refer to this directory as the WL_HOME directory, distinguished from the Oracle Middleware Home directory, which, in this example, is C:\Oracle\Middleware. Thus, the complete path of the WebLogic Server Home in this example is C:\Oracle\Middleware\wlserver.

Under the WebLogic Server Home (WL_HOME), you’ll find the following directory structure:

- common
- modules
- plugins
- samples (if you chose to install the sample applications)
Chapter 1: Installing Oracle WebLogic Server 12c and Using the Management Tools

- server
- sip

The bin directory under the WL_HOME server directory contains the `startNodeManager` script to start the Node Manager. During the installation of WebLogic Server shown in this chapter, we chose to create the sample domains offered by Oracle. These are the `medrec`, `medrec-spring`, and `wl_server` domains. These domains are located under the `user_projects` directory, in the domains folder. The next section explores the contents of these domain directories, all of which have the same structure.

**WebLogic Server Domain Directory**

Each domain that you create will have the following directory structure, under the Oracle_Home/user_projects/domains directory:

- autodeploy
- bin
- common
- config
- console-ext
- init-info
- lib
- nodemanager
- security
- servers

Under the bin directory of each domain is where you’ll find the various scripts to start and stop the Admin and Managed Servers, such as `startWebLogic.cmd` and `stopWebLogic.cmd`. Note that UNIX versions of these scripts are also located in this directory. The all-important domain configuration file, `config.xml`, is stored in the domains/config directory.

For now, it’s enough to be aware of the basic structure of a WebLogic domain. Chapter 3 details how to configure a domain, and I will postpone the detailed examination of a domain directory’s contents until that point.

**The WebLogic Server Sample Applications**

To demonstrate the basic features of the Administration Console, I’ll use one of the three sample domains created during the installation when we chose to install the samples. The code examples provided by Oracle are located in various domains, all under the Oracle_Home\user_projects\domains directory. I understand that most readers don’t need to install the sample applications because they already have a working knowledge of WebLogic Server. For those new to WebLogic Server, however, the sample applications will help you understand web applications, and the sample domains will help you learn how to administer and manage WebLogic Server.
NOTE

All the sample domains that the Configuration Wizard creates for you during the WebLogic Server installation (if you choose to install the samples) are located, by default, in the ORACLE_HOME\user_projects\domains directory (C:\Oracle\Middleware\Oracle_Home\user_projects\domains directory on my server, since ORACLE_HOME is defined as C:\Oracle\Middleware\Oracle_Home). You can specify alternative locations for the domain directories.

The WebLogic Server samples contain two different types of applications to familiarize you with Java EE applications and to help you understand how Oracle WebLogic Server works. The first set of applications is part of the domain named wl_server, and the domain’s Admin Server is named Examples Server. The wl_server domain contains Oracle WebLogic Server API examples designed to show you how to implement Java EE APIs and related Oracle WebLogic Server features. Oracle also provides a web application called examplesWebApp, which includes several of these examples. In addition, there’s a full-blown sample Java EE web application by the name of Avitek Medical Records as part of the domain named medrec. When you choose to install the examples, two versions of the Avitek Medical Records application are installed for you. The first one is the MedRec application designed to demonstrate various features of the Java EE platform. The second application, called MedRec-Spring, is the same as the MedRec application, but it is created using the Spring Framework and is part of the medrec-spring domain.

Oracle recommends that you start working with the wl_server domain to understand the basics of Java EE programming and WebLogic Server. If you’re already familiar with both of these, check out the Avitek Medical Records and the Avitek Medical Records (Spring) sample applications. Both of these present realistic examples that show how to develop and deploy full-blown Java EE applications. The two applications also serve as great learning tools for Java EE developers and for WebLogic Server administrators who wish to understand application deployment concepts.

Key Environment Files

Let’s take a close look at the key environment files you’ll be using while managing your WebLogic Server. The two key WebLogic Server environment files in a Windows server are the setDomainEnv.cmd and the setWLSEnv.cmd files. These two files have similar counterparts in the UNIX environment, named, for example, WLSEnv.sh and so on.

The DomainEnv.cmd File

There’s a setDomainEnv.cmd file for each domain you create with the Configuration Wizard. This script sets up the environment correctly so you can start WebLogic Server in a domain.

When you invoke the setDomainEnv.cmd file, it invokes the following variables before calling commEnv to set the other variables:

- **WL_HOME**  The home directory of your WebLogic installation.
- **JAVA_VM**  The desired Java VM to use. You can set this environment variable before calling this script to switch between Oracle and BEA or just use the default.
- **JAVA_HOME**  Location of the version of Java used to start WebLogic Server. Depends directly on which JAVA_VM value is set by default or by the environment.
- **MEM_ARGS**  The variable to override the standard memory arguments passed to Java.
Chapter 1: Installing Oracle WebLogic Server 12c and Using the Management Tools

- **PRODUCTION_MODE**  The variable that determines whether Weblogic Server is started in production mode.

- **DOMAIN_PRODUCTION_MODE** Determines whether the workshop-related settings like the debugger, testconsole, or iteratedev should be enabled. You can only set these using the @REM command-line parameter named production. Specifying the production command-line parameter forces the server to start in production mode.

- **WLS_POLICY_FILE**  The Java policy file to use. Set this environment variable to specify a policy file; otherwise, this script assigns a default value.

Other variables used in this script include:

- **SERVER_NAME**  Name of the WebLogic server.

- **JAVA_OPTIONS**  Java command-line options for running the server (tagged on to the end of JAVA_VM and MEM_ARGS).

- **PROXY_SETTINGS**  Tagged on to the end of the JAVA_OPTIONS variable; however, this variable is deprecated and should not be used. Use JAVA_OPTIONS instead.

The *setWLSEnv.cmd* File

The *setWLSEnv.cmd* script file configures the environment for development with WebLogic Server. It sets the following variables:

- **WL_HOME**  The root directory of your WebLogic installation.

- **JAVA_HOME**  Location of the version of Java used to start WebLogic Server. This variable must point to the root directory of a JDK installation and will be set for you by the Installer.

- **PATH**  Adds the JDK and WebLogic directories to the system path.

- **CLASSPATH**  Adds the JDK and WebLogic jars to the CLASSPATH.

Other variables that *setWLSEnv.cmd* takes are

- **PRE_CLASSPATH**  Path style variable to be added to the beginning of the CLASSPATH.

- **POST_CLASSPATH**  Path style variable to be added to the end of CLASSPATH.

- **PRE_PATH**  Path style variable to be added to the beginning of the PATH.

- **POST_PATH**  Path style variable to be added to the end of the PATH.

Starting the Examples Server

The Examples Server is the Admin Server for the *wl_server* domain. It contains basic web application examples. To launch the Examples Server, run the following two commands, the first to set up the environment and the second to start the WebLogic Server instance. Once you successfully run these two scripts, the Admin Server for the sample domain *wl_server* is started.

```cmd
C:\Oracle\Middleware\Oracle_Home\user_projects\domains\wl_server\bin\setDomainEnv.cmd
C:\Oracle\Middleware\Oracle_Home\user_projects\domains\wl_server\bin\startWebLogic.cmd
```
The directory from which we start the Admin Server for the domain `wl_server`, `C:\Oracle\Middleware\Oracle_Home\user_projects\domains\wl_server` is also called the DOMAIN_HOME (for the server `wl_server`).

**TIP**
Because they’re purely for learning purposes, do not install the WebLogic Server Examples on your production servers. Leaving them on a production server introduces vulnerabilities that can be exploited by hackers.

Once the Administration Server starts booting, you can follow the boot sequence in the command window that pops up. You’ll also see a separate command window that shows the launching of the Derby database for the Examples Server. Once the Administration Server boots, you’ll see the following in the command window:

...  
Calling `setDomainEnv` in this domain  
Modifying classpath for the samples  
Classpath has successfully been set to:  
C:\Oracle\Middleware\Oracle_Home\user_projects\applications\wl_server\examples\build\serverclasses;C:\Oracle\Middleware\Oracle_Home\user_projects\applications\wl_server\examples\src;  
C:\PROGRA~1\Java\JDK17-1.0_4\lib\tools.jar;  
C:\Oracle\MIDDLE-1\ORACLE-1\wlserver\server\lib\weblog  
...  
C:\Oracle\MIDDLE-1\ORACLE-1\wlserver\server\lib\xqrl.jar;  
C:\Oracle\Middleware\Oracle_Home\user_projects\applications\wl_server\examples\build\clientclasses  
Script has completed successfully  
C:\Oracle\Middleware\Oracle_Home\user_projects\domains\wl_server>

Once the environment is set, execute the `startWebLogic.cmd` script to start the server:

C:\Oracle\Middleware\Oracle_Home\user_projects\domains\wl_server>start WebLogic.cmd

JAVA Memory arguments:  
-Xms256m -Xmx512m -XX:CompileThreshold=8000 -XX:PermSize=128m -XX:MaxPermSize=256m  
...  
CLASSPATH=C:\Oracle\Middleware\Oracle_Home\user_projects\applications\wl_server\  
*************

starting weblogic with Java version:  
java version "1.7.0_40"  
log file  
C:\Oracle\Middleware\Oracle_Home\user_projects\domains\wl_server\  
servers\AdminServer\logs\AdminServer.log is opened. All server side  
log events will be written to this file.>

...  
<Started the WebLogic Server Administration Server "AdminServer" for  
domain "wl_server" running in development mode.>
In addition to the main Windows command console (don’t close it or else your server instance will promptly die!) that displays the server lifecycle messages throughout the server’s life, you’ll also see another window that shows that the default Derby database server is also up and ready to receive requests. (You can change the database server to a different server, say Oracle Database 12c, later on in the process.) Here are the Derby server window’s messages when it starts:

2013-10-19 11.05:00AM CDT: Security manager installed using the Basic server security policy.
2013-10-19 11.05:00AM CDT: Apache Derby Network Server - 10.6.1.0 - (938214) started and ready to accept connections on port 1527

Once you see that the WebLogic Server has started in RUNNING mode, the Examples Server is ready to use. Your browser will automatically launch at this point and display the Oracle WebLogic Server Samples Introduction Page, which is the gateway to the sample applications. If, for some reason, the browser doesn’t automatically launch, you can go to the following URL to see the page:

http://localhost:7001/examplesWebApp/index.jsp

Note that port 7001 must be available for you to access the Administration Console for this domain. Remember that the default credentials to log into the Administration Console are weblogic/welcome!

To launch one of the other sample applications, for example, the Avitek Medical Records Sample Application, run the following command, which starts the Admin Server for the medrec domain:

C:\Oracle\Middleware\Oracle_Home\user_projects\domains\medrec\bin\startWebLogic.cmd

This command starts the application and displays the startup page. You can click the Start Using MedRec button to start the application. You can also start the Administration Console to manage the MedRec domain by clicking the Start The Administration Console button.

Stopping the Server
You can stop a running server by closing the command window or by pressing CTRL-C in the command window. In production environments, however, you use a shutdown script to stop the servers. You can use the following command script to shut down the Admin Server for the sample domain medrec, for example:

C:\Oracle\Middleware\Oracle_Home\user_projects\domains\medrec\bin\stopWebLogic.cmd

Note that you need to point your browser toward a different port number to access the Administration Console for each of these same servers. By default, the example domains run in the development mode. You can configure all servers in a domain to run in production mode by
clicking Domain on the Administration Console Home page and checking the Production Mode box. You must first click the Lock & Edit button in the Change Center to activate the change. You must also restart the server so it can start in production mode. All servers in this domain will now run in production mode. Note that you can’t toggle back to development mode once you enable production mode—you can disable the production mode only at the Admin Server startup command line by specifying the \-Dweblogic.ProductionModeEnabled=false option.

## Upgrading Oracle WebLogic Server

The latest version of Oracle WebLogic Server, as of the writing of this book, is the 12.1.2 release. You can upgrade to this release from earlier versions of WebLogic Server. When you upgrade Oracle WebLogic Server, not only must you install the new software, of course, but you also have to upgrade the security providers, the Node Manager, and the existing domains as well as any remote Managed Servers. If you’re upgrading from WebLogic Server versions prior to WebLogic Server 10.3.1, you must follow a two-step process to upgrade to version 12.1.2:

1. First upgrade to WebLogic Server 10.3.6, using the instructions in the Oracle manual Upgrade Guide to WebLogic Server 10.3.6. As part of this, you must also run the WebLogic Server 10.3.6 Domain Upgrade Wizard to upgrade the domains.

2. Upgrade WebLogic Server 10.3.6 to WebLogic Server 12.1.2.

The following sections provide a summary of the upgrade procedures to upgrade from WebLogic Server installation release 10.3.6 to 12.1.1.

You must upgrade the WebLogic domain when you upgrade to WebLogic Server 12.1.2, by upgrading the domain directory on each computer in the domain. It’s important to understand, however, that most Java EE applications, including web applications, EJBs, and so on, can be run without any modifications in the WebLogic Server 12.1.2 environment.

Before embarking on a major upgrade project, of course, you must verify that all components in your environment, such as databases, load balancers, and firewalls are compatible with WebLogic Server 12.1.2.

### Upgrade Tools

What used to be called an upgrade of a domain in earlier releases is now called *reconfiguring a domain* in Oracle WebLogic Server 12.1.2, and in Oracle WebLogic Server 12c, the new Oracle Fusion Middleware Reconfiguration Wizard (hereafter called the Reconfiguration Wizard) has replaced the old Domain Upgrade Wizard. You can reconfigure a WebLogic domain using two methods:

- You can run the Reconfiguration Wizard.
- You can reconfigure a domain from the command line with the WebLogic Scripting Tool.

Oracle provides several reconfiguration templates for Fusion Middleware products to make upgrading WebLogic Server and Fusion Middleware installations easy. The Wizard applies the appropriate reconfiguration templates. The templates then update the domain version to the current version.

Oracle recommends that you use the WLST script to reconfigure a domain when you can’t run the Reconfiguration Wizard for any reason.
Chapter 1: Installing Oracle WebLogic Server 12c and Using the Management Tools

Obviously, you don’t have to use the Reconfiguration Wizard, but as with any GUI wizard, using it will certainly make life easier for you during an upgrade. You can, for example, manually upgrade a domain by installing the software for the current release, updating the domain script files to point to the new installation, and updating the CLASSPATH to remove outdated information. As you will see, the Reconfiguration Wizard can prevent many headaches with its automated approach to the upgrade.

Upgrade Procedures

When you upgrade to a newer release of WebLogic Server, in most cases, you don’t have to upgrade the web applications you deploy. The latest release of WebLogic Server, 12.1.2, will work with all applications you created on earlier WebLogic Server releases. You do, however, have to upgrade several server components:

- Custom security provider
- Node Manager
- Domains
- Remote Managed Servers

In addition, you need to ensure that any external resources WebLogic Server connects to, such as an Oracle database, for example, are compatible with the new release. The following sections briefly describe the upgrade procedures. Before you start the actual upgrade process, however, do the usual due diligence effort, such as verifying the supported configurations and the compatibility of the various software applications, as well as doing an inventory of your current WebLogic Server environment. As with any upgrade of a server, back up your applications, shut down all running servers, and start by installing the new release of the Oracle WebLogic Server software.

As mentioned earlier, you may not have to do much to make your current applications run on the latest release of WebLogic Server. However, you must upgrade the security providers, the domain, the Node Manager, and the remote Managed Servers. The following sections briefly explain each in turn.

Upgrading the Security Provider

When upgrading the security providers, the Reconfiguration Wizard upgrades the JAR files for security providers so the providers can work under a 12.1.1 environment. If you’re using a custom security provider in the 7.0 or 8.0 release, the Reconfiguration Wizard can upgrade those providers to run in a 12.1.1 environment as well.

Upgrading the Node Manager

Upgrade the Node Manager (on all machines where it currently runs) only if you intend to use any customized versions in the new environment. Otherwise, there’s nothing for you to do here during an upgrade. Once the upgrade is completed, you must enroll the Node Manager with all machines, and Chapter 2 shows you how to do this.

Upgrading Existing Domains

Before upgrading any remote Managed Servers, upgrade the domain on the machine where the Admin Server resides. If you have any Managed Servers on the same server as the Admin Server, you don’t have to upgrade them. Upgrading the domains updates the config.xml file—the key domain configuration file—and also updates persistent data in the JMS file stores.
Upgrading the Remote Managed Servers

During an upgrade, you need to upgrade just those Managed Servers that reside on remote servers. Before upgrading, you must first copy two important files (config.xml and SerializedSystemIni.dat) from the root directory of the original domain directory of the Admin Server to the root directory of the remote Managed Server domain.

If there’s no Administration Server on the remote machine, you can use one of two methods to update the Managed Server domains on the remote machine:

- You can execute the pack -managed=true command to generate the domain template JAR and move the JAR to the remote machine, and then use the unpack utility to create the Managed Server domain (you’ll learn about the pack/unpack commands in Chapter 3).
- Alternatively, you can use the WLST writeTemplate command to update the Managed Server domain on the remote machine. The WLST writeTemplate command has been modified in the WebLogic Server 12c release to work in the online mode, letting you update domains that run on remote machines using WLST instead of being limited to the pack/unpack utilities.

Reconfiguring a WebLogic Domain

Back up your domain before running the Reconfiguration Wizard, as the configuration process can’t be reversed. To return the domain to its original state, you need the backup. The old Domain Upgrade Wizard automatically backed up the domain before starting the upgrade process, but with the Reconfiguration Wizard, you must back up the domain yourself.

Reconfiguring a domain is a long drawn-out affair, with multiple configuration screens and choices. You must consult the Oracle WebLogic Server 12c documentation for the complete upgrade procedures. However, a summary of the upgrade process will help you understand the process, and that’s what I provide next. Let’s first review the domain upgrade process using the Oracle Middleware Reconfiguration Wizard. After that, you’ll learn how to upgrade a domain using WLST.

Reconfiguring with the Reconfiguration Wizard

To upgrade a domain using the Reconfiguration Wizard, follow these general steps:

1. Start the Reconfiguration Wizard with the following command, after moving to the ORACLE_HOME\oracle_common\common\bin directory as shown here.

   $ cd C:\Oracle\Middleware\Oracle_Home\oracle_common\common\bin>
   $ C:\Oracle\Middleware\Oracle_Home\oracle_common\common\bin> reconfig.cmd

   **NOTE**
   You can also run the Reconfiguration Wizard by going to Programs | Oracle | WebLogic Server 12c | Tools | Reconfiguration Wizard. Once the Oracle Middleware Reconfiguration Wizard starts, it shows the Select Domain page.
2. Specify the location of the domain you want to upgrade on the Select Domain page, shown here:

```
Click Next after ensuring that the full path to the domain directory of the domain you wish to upgrade is selected.
```

3. The Reconfiguration Setup Progress page shows the progress of the application of the reconfiguration templates. When the application of the templates is completed, click Next.

4. On the Domain Mode And JDK page, select the JDK you want the domain to use. Click Next.

5. (optional) Depending on your domain configuration, different additional screens may appear after this point.

6. On the Advanced Configuration page, check the boxes of all categories for which you want to perform configuration tasks. Click Next.

7. On the Configuration Summary page, review and then click Reconfig to complete the domain reconfiguration.

8. When you see the Reconfiguration Success page and the message “Oracle WebLogic Server Reconfiguration Succeeded,” the domain has been updated successfully. Click Finish to exit the Reconfiguration Wizard.

### Reconfiguring a Domain Using WLST

You haven’t yet learned how to use the WLST scripting tool, but you will shortly! You can reconfigure a domain using WLST in offline mode.
Here’s an example showing how to reconfigure a domain called _my_domain with WLST:

1. Open the domain for upgrade: vb
   
   ```
   wls:/offline> readDomainForUpgrade('c:/domains/my_domain')
   ```

2. Save the updated domain:
   
   ```
   wls:/offline/my_domain> updateDomain()
   ```

3. Once you’re finished upgrading the domain, close it:
   
   ```
   wls:/offline/my_domain> closeDomain()
   ```

**Complete Node Manager Configuration**

Regardless of whether you upgrade a domain with the Reconfiguration Wizard or WLST commands, you must complete the Node Manager configuration following the domain update. Here are the steps:

1. Create a `nodemanager` directory under the `ORACLE_HOME/oracle_common/common` directory of the new WebLogic Server installation.

2. Copy the `nodemanager.properties`, `nodemanager.domains`, and the `nm_data.properties` (if there’s one) files from the previous installation to the new nodemanager directory.

3. Copy the `security/SerializedSystemIni.dat` file to the same directory under nodemanager by creating the security directory under nodemanager.

4. Edit the `nodemanager.properties` file in the following way:
   
   - Update `DomainsFile` to point to `ORACLE_HOME/oracle_common/common/nodemanager/nodemanager.domains` file.
   - If the file contains a `javaHome` property setting, remove it.
   - Update `JavaHome` to point to the jre directory for the JDK that you’re using for WebLogic Server 12.1.2.
   - Update `NodeManagerHome` to point to `ORACLE_HOME/oracle_common/common/nodemanager`.
   - Update `LogFile` to point to `ORACLE_HOME/oracle_common/common/nodemanager/nodemanager.log`.

   If you’re using your own security certificates, point to the location of those certificates in the `nodemanager.properties` file. If you are using the WebLogic Server demo certificate instead, run `Certgen` to create a demo keystore for the new installation.

   Once you’re all done, run `startNodeManager.cmd` from the `ORACLE_HOME\wlserver\server\bin` directory to ensure that the Node Manager starts.

**Using OPatch to Patch Oracle WebLogic Server**

In the previous release, you could patch Oracle WebLogic Server software with the Smart Update utility for both maintenance patches and maintenance packs. In WebLogic Server 12c, Smart Update isn’t supported. You must use the `OPatch` utility to apply patches for Oracle WebLogic Server 12c.
TIP
You can use the Opatch utility to patch not only WebLogic Server software, but also Oracle Fusion Middleware installations.

You can find the OPatch utility in the ORACLE_HOME/Opatch directory. To view the list of commands available to you (on a Windows server), run the following command:

```
$ opatch.bat -help
```

Patching a WebLogic Server installation using OPatch is extremely simple. Here are the basic steps you must follow:

1. Get the patches you need to apply from the Oracle Support site.
2. Review the README.txt file for the patch to see what you need to do before applying a patch.
3. Check for any patch prerequisites with the following command:

   ```
   $ opatch apply /oracle/middleware/oracle_home/wl_server -report
   ```

4. Apply the patch with the apply command:

   ```
   $ opatch apply /oracle/middleware/wl_server/patches/15221446 /* patch number
   ```

   You can apply multiple patches with a single command, by specifying the napply option instead of the apply option.

5. Verify the patch application with the lsinventory command:

   ```
   $ opatch lsinventory
   ```

6. You can rollback a patch by using the rollback command:

   ```
   $ opatch rollback -id 15221446
   ```

   The nrollback option lets you rollback multiple patches with a single command.

Using the Administration Console
WebLogic Server offers a browser-based Administration Console to help manage a domain. The Admin Server hosts the Administration Console application, and you can access the Console from any browser that has network access to the Admin Server.

The Administration Console lets you administer your entire domain—the server instances, web applications, modules, and all the resources that the applications and modules need to use. Not only can you configure and monitor the servers, but also you can create new server instances with the Console. The Administration Console also helps you tune your applications. The Console makes performing various configuration and management tasks easy, without you’re having to learn how to use the underlying JMX API, which is what you need to configure the domains manually. In Chapter 2, you’ll learn the various ways in which you can start and stop WebLogic Server instances. The easiest, as well as the recommended way to manage your servers is through the Administration Console. You can even edit and save changes to the domain configuration file, config.xml, through the console. Throughout this book, you’ll learn how to configure various aspects of WebLogic Server through the Administration Console.
This seems like the right place to point out that in Oracle WebLogic Server 12c, you can also manage Weblogic Server through Fusion Middleware Control. You can manage the following aspects of WebLogic Server through Fusion Middleware Control:

- Starting up and shutting down servers
- Clustering servers
- Managing WebLogic Server services, such as database connectivity (JDBC) and messaging (JMS)
- Deploying applications
- Monitoring server and application performance

**TIP**
If you’re new to the Administration Console, it pays to check out the excellent help material you can access by clicking the How Do I link, where you’ll find crystal clear steps for performing any task within the Administration Console.

Because the Administration Console is linked to a domain, until you create a domain, the Administration Console does not exist. When you create a domain, by default, a single Admin Server is created for you. It’s the Admin Server that runs the web-based Administration Console that enables you to manage the entire domain. Thus, you must first start the Admin Server before you can access the Administration Console. Once you create a domain, you can access the Administration Console at the default port 7001, but you can also assign it any other free port number.

**NOTE**
You can disable the Administration Console by clearing the Console Enabled box on the Administration Console’s configuration page for the Admin Server. If you do this, you can manage the domain only with management APIs.

Any configuration changes you make through the Administration Console will update the config.xml, which is the domain configuration file.

**Logging In to the Administration Console**
Once you’ve created a domain, launch the Admin Server first. Once the Admin Server is in running mode, you can access the Administration Console and manage the domain. Invoke the Administration Console by using the following URL:

http://localhost:7001/console

Note that 7001 is the default port that WebLogic Server uses. You can set the port to any valid port number you choose.

In the following example, as explained in the preceding section, let’s use the Examples Server (Admin Server for the wl_server domain) provided by the Installer. Launch the Examples Server by going to Start | Oracle WebLogic | WebLogic Server 12cR1 | WebLogic Server. Because every
domain will host its own Admin Server, if you are running multiple domains on your machine, each Admin Server will have to bind to a different port. For example, you can access the Administration Console for the \texttt{wl\_server} domain using this address:

\url{http://localhost:7001/console}

Meanwhile, you can access the Administration Console for the \texttt{medrec\_spring} domain by entering

\url{http://localhost:7011/console}

If you’re using Secure Sockets Layer (SSL) to start your Admin Server, use \texttt{https} instead of \texttt{http}, as shown here, and note that you use a different port number from that of the non-SSL port:

\url{https://localhost:7002/console}

\textbf{TIP}

\textit{If you’ve configured a proxy server, configure your browser so it doesn’t direct the Admin Server requests to the proxy. If you’re running both the Admin Server and your web browser on the same server, make sure the requests are sent to the local host (or IP 127.0.0.1) and not to the proxy server.}

The default administrative username for the Admin Server is \texttt{weblogic}, and the default password is \texttt{welcome1}. You may also log in later by choosing a username that you granted to a default global security role. If you grant the default global security role \texttt{Admin} to a user, for example, that user can perform any task using the Administration Console. If you gave another user a more limited security role, such as \texttt{Deployer}, \texttt{Monitor}, or \texttt{Operator}, the user won’t be able to edit the configuration data; these users can only view, not modify, the configuration data.

On the Administration Console login page, shown in Figure 1-1, enter the default username and password (\texttt{weblogic} and \texttt{welcome1}, respectively), or for a custom domain, use the username and password combination you chose during domain creation. You can log out of the Console by clicking the Log Out button at the top of the right pane of the console.

Once you successfully log in to the Administration Console, you’ll see the Home page, as shown in Figure 1-2. Notice that the Home page of the Administration Console contains two panes. Resources and servers are listed in the left pane. At the top of the right pane are the Log Out and Preferences buttons. When you click a server under a domain, the relevant configuration items will show up on the right; here, you can check or modify the server’s configuration.

**Navigating the Administration Console**

The tree menu on the left pane of the Home page provides quick access to functionality that allows you to manage not only the servers and clusters but also the configuration of resources such as JMS servers and data sources. For example, by expanding \texttt{wl\_server | Services | Data Sources}, you will see a complete list of data sources configured on this domain. At the top of the left pane, notice the Change Center, which helps you view and modify server configurations. Right underneath is the Domain Structure section. In this section, there are several key items that help you manage WebLogic Server. I explain these in the following sections.
FIGURE 1-1. The Oracle WebLogic Server Administration Console login page

FIGURE 1-2. The Administration Console Home page
Environment
You’ll find the following items under Environment:

- Servers
- Clusters
- Virtual Hosts
- Migratable Targets
- Coherence Servers
- Coherence Clusters
- Machines
- Work Managers
- Startup and Shutdown Classes

For example, if you click Servers, you’ll then see in the right-hand pane the Configuration page for the lone server in the domain, examplesServer, which is the Admin Server for this domain (wl_server), as shown in Figure 1-3.
Deployments
This group takes you to the Deployments page, from where you can manage the enterprise applications or web modules you’ve deployed. You can start, stop, redeploy, or remove an application or module from this page.

Services
Important resources you can manage include messaging, which consists of Java Messaging Service (JMS) servers and JMS modules; Java Database Connectivity (JDBC) data sources; and Java Transaction APIs (JTA).

Security Realms
This group contains all security realms you have configured for this domain. Select a realm from under Security Realms in the left pane. When you do this, all the subnodes for all the security providers in a realm appear in the right pane, providing you access to a realm’s users, groups, and roles. The Administration Console lets you configure any aspect of a security realm.

Interoperability
This group contains features that allow your applications to operate with Tuxedo Services, such as the WebLogic Tuxedo Connector and Jolt, a Java-based client that manages requests made to Oracle Tuxedo Services.

Diagnostics
This group contains diagnostic modules and diagnostic images (snapshots) to help manage the WebLogic Diagnostic Framework (WLDF). You can also configure Simple Network Management Protocol (SNMP) agents from here.

Using the Change Center
From the Administration Console’s Change Center, you can lock a domain’s configuration while you’re changing any configuration attributes. By default, the Change Center is always enabled when you run a server in production mode and disabled in development mode. To make permanent configuration changes from the Administration Console, you must first obtain a lock, make your changes, and then activate them. By doing so, other accounts are prevented from making changes during your edit session, preventing conflicting or overlapping configuration changes.

Instead of making configuration changes piecemeal, you can make multiple changes and activate them all at once. You can click the View Changes and Restarts button to view all the pending changes that you have applied but not activated yet. The Change List page shows you all changes that are saved but not yet activated. By clicking the Restart Checklist tab, you can view the changes that have been activated but are waiting for a server restart before they become effective.

In development mode, the domain configuration locking feature is disabled by default; that is, the Automatically Acquire Lock And Activate Changes property is enabled. Automatic locking means you don’t have to acquire a lock explicitly on the domain configuration before making any changes to it. In the top-left corner of the Administration Console, you’ll see the following note: “Configuration editing is enabled. Future changes will automatically be activated as you modify, add or delete items in this domain.” This means that when you make and save a configuration change, it’s automatically activated. This is fine for a development environment, but for a production environment, you should always enable the locking feature. In fact, when you run the server in production mode, you don’t have the option to set up automatic acquisition of configuration
locks and activation of changes. The Automatically Acquire Lock And Activate Changes property is exclusive to servers running in development mode.

You can enable domain configuration locking by going to the right-hand pane of the Administration Console and clicking Preferences in the menu at the top of the page. At the bottom of the page, you’ll see the box Automatically Acquire And Activate Changes. You can leave this box checked for a development domain so you can make quick configuration changes on the fly, but it should always be unchecked for a production domain. Clear this option and click Save. Once you click the Release Configuration button in the Change Center, the Lock & Edit button appears, as shown in Figure 1-4.

Once you enable domain configuration locking, you must use the Lock & Edit button to make any configuration changes, including editing, adding, or deleting any type of configuration attributes. The main purpose behind all this is to ensure that other sessions don’t make configuration changes while you’re trying to make changes. If you don’t click the Lock & Edit button in the Change Center, the server won’t even let you start the configuration process—the check boxes for selecting the server or a subcomponent you want to configure will be grayed out. Once you complete any configuration changes and save them, you must click the Activate Changes button to make those changes effective. As you’ll see later, some configuration changes require that you restart the server.

To illustrate how to use the Lock & Edit feature, the following example shows you how to disable the Administration Console (something you may want to do to prevent access to the...
Console in a production environment, which is a configuration change you can make from the Console:

1. Click Lock & Edit, as shown previously in Figure 1-4. This locks the configuration MBean hierarchy so you can make changes. Now the Lock & Edit button is grayed out, but the Release Configuration button becomes clickable so you can back out before you make your configuration changes.

2. In the Domain Structure section on the left, click the name of your domain—in the case of the Examples Server, this would be \textit{wl\_server}.

3. From the Configuration tab on the right pane of the Console, click the General tab and then click Advanced at the bottom of the page. Uncheck the Console Enabled option and click Save. When you click Save, you’ll see the following message (in green) on the top of the page where you made the change, confirming that the change was successful:

\textit{Settings Updated Successfully}

4. Finally, you’ll see two new buttons in the Change Center: Activate Changes and Undo All Changes, as shown in Figure 1-5. Click Activate Changes in the Change Center to make the change effective.

\textbf{FIGURE 1-5.} The Activate Changes button in the Change Center
After you click the Activate Changes button in the Change Center, you’ll see the following message (in green) at the top of the right-hand pane:

All changes have been activated. However 1 item(s) must be restarted for the changes to take effect.

The reason the message states that “1 item(s) must be restarted” is because disabling the Console is a nondynamic change that requires a server restart.

NOTE
Some configuration changes are dynamic and, therefore, go into effect right away; other changes are nondynamic and require a server restart.

You’ll also see the following in the command console, following the change you just made:

<Oct 25, 2013 1:37:51 PM CDT> <Warning> <Management> <BEA-141239>
The non-dynamic attribute ConsoleEnabled on weblogic.management.configuration.DomainMBeanImpl@d5bf4c12([wl_server]) has been changed. This may require redeploying or rebooting configured entities.

<Oct 25, 2013 1:37:51 PM CDT> <Warning> <Management> <BEA-141238> <A non-dynamic change has been made which affects the server examplesServer. This server must be rebooted in order to consume this change.>

Once you disable the Administration Console, you can reenable it only through the WebLogic Scripting Tool (WLST). Once the Admin Server is started, invoke WLST by navigating to Start | Programs | Oracle | Oracle Home | WebLogic Server 12c | Tools | WebLogic Scripting Tool and issue the following commands at the WLST command line:

Initializing WebLogic Scripting Tool (WLST)...
Jython scans all the jar files it can find at first startup.
Depending on the system, this process may take a few minutes to complete,
and WLST may not return a prompt right away.
Welcome to WebLogic Server Administration Scripting Shell
Type help() for help on available commands
wls:/offline>
wls:/offline> connect("weblogic", "welcome1")
Connecting to t3://localhost:7001 with userid weblogic ...
Successfully connected to Admin Server 'examplesServer' that belongs to domain 'wl_server'.
Warning: An insecure protocol was used to connect to the server.
To ensure on-the-wire security, the SSL port or Admin port should be used instead.
wls:/wl_server/serverConfig> edit()
Location changed to edit tree. This is a writable tree with DomainMBean as the root. To make changes you will need to start
an edit session via startEdit(). For more help, use help(edit)
wls:/wl_server/edit> startEdit()
Starting an edit session ...
Started edit session, please be sure to save and activate your changes once you are done.
wls:/wl_server/edit !> cmo.setConsoleEnabled(true)
wls:/wl_server/edit !> save()
Saving all your changes ... 
Saved all your changes successfully.
wls:/wl_server/edit !> activate()
Activating all your changes, this may take a while ...
The edit lock associated with this edit session is released once the activation is completed.

Working with the Administration Console

You already know how to log into the Administration Console. The following sections show how to log out of the Console and to set Console preferences.

Logging Out of the Console

To log out of the Administration Console, click the Log Out button at the top of the right-hand pane. Logging out of the Administration Console doesn’t affect the Admin Server. To log back in, use the URL for the console—http://<hostname>:port/console. When you shut down the Admin Server from the Administration Console, the Console immediately shuts down and won’t be available until you manually restart the Admin Server. Once you restart the Admin Server, you can log back in to the Console by using the now familiar URL:

http://127.0.0.1:7001/console

Setting Console Preferences

You can set Administration Console preferences by clicking the Preferences button at the top of the right-hand pane. You can select several configuration-related properties from the Preferences page, including whether the server asks for confirmation of operations. You can also choose your preference for whether the server issues a warning message when a user logs out with an active domain configuration lock for a resource in place. Note that when this happens, other users won’t be able to lock that resource for making their own configuration changes. The lock holder must either release the configuration changes or activate them first.

Changing the Console’s URL

You can change the Console’s URL (by default, http://localhost:7001/console) to a different URL. To change the Console’s URL, on the Configuration page for the domain, click General and then Advanced at the bottom of the page. Enter the context path in the Console Context Path box. If you specify a new context path named newconsole, for example, you can then use the following URL to access the Console: http://localhost:7001/newconsole.

Changing the Listen Port and Listen Address

To change the listen port or listen address that you use to access the Administration Console, you must change those settings for the domain’s Admin Server. You can change the following network-related configuration attributes from the Administration Console. Go to the Admin Server’s Configuration page and click General. From this page, you can configure the following network-related settings:

- **Listen Address**  This is the IP address or DNS name for the server.
- **Listen Port**  Enter the default TCP/IP port for listening for non-SSL connection requests.
Chapter 1: Installing Oracle WebLogic Server 12c and Using the Management Tools

Listen Port Enabled  This lets you enable or disable the default non-SSL listen port.

SSL Listen Port  Enter the TCP/IP port on which to listen for secure SSL connection requests.

SSL Listen Port Enabled  If you haven’t enabled the optional administration port, both application traffic and administrative traffic will go through the normal listen port and the SSL listen port. If you’ve enabled the administration port, then the administrative traffic will only go through the administrative port.

The preceding is a very brief summary of what you can do with the Administration Console. Throughout this book, you’ll have plenty of chances to review the many capabilities of the Administration Console, as we discuss topics such as deployment, security, configuration management, and diagnostics.

A Brief Introduction to the Node Manager
The Node Manager, as mentioned earlier in this chapter, is a purely optional process (or daemon) that lets you remotely manage both the Admin Server and all Managed Servers within that domain. If you’re in a production environment with high availability requirements, Oracle recommends that you use the Node Manager to manage the servers running on different machines. In Chapter 2, you’ll find a detailed explanation of how to configure the Node Manager and how to manage servers using WLST and the Node Manager together.

Unlike the Admin Server, of which there’s only a single instance running per domain, you must run the Node Manager on each of the servers (machines) on which you plan to run the Admin Server or one of the Managed Servers. You don’t have to install the Node Manager separately—each installation of WebLogic Server comes with the Node Manager. You just need to start the Node Manager service or process on each of the machines running WebLogic Server instances. Thus, if you have WebLogic Server instances running on five different servers, you must have five Node Manager processes running, one per machine.

Oracle WebLogic Server offers you two types, or versions, rather, of the Node Manager—one a Java-based and the other a script-based version. Although both versions offer the same functions, you need to configure them differently. Also, different security considerations apply to the two versions, with the Java-based version offering you more security features than the script-based version. You can configure the Java-based Node Manager with the nodemanager.properties file, as shown in Chapter 2. The Java-based version allows you to use SSL, and the script-based version offers you the capability to manage servers over an SSH-enabled (or RSH-enabled) network once you copy the scripts to the remote servers.

You can run the Node Manager as a Windows service or an OS daemon so it automatically starts when you reboot the server. Chapter 2 shows you how to run the Node Manager as an operating system service, post installation. The Configuration Wizard gives you the option to install the Node Manager as an operating system service, which Oracle recommends you do. When you install the WebLogic Server software, choose the Java-based Node Manager if you’re working on a Windows or a UNIX platform and wish to run the Node Manager as an operating system process.

NOTE
The Node Manager isn’t supported on all platforms, so check the Oracle documentation to ensure it’s supported on your platform.
The script-based Node Manager uses UNIX-style shell scripts, so you can run it only on UNIX and Linux systems. Oracle recommends that you run this version as an operating system service to enable automatic restarts.

Choosing between the Java-based and script-based versions of the Node Manager isn’t really hard. Only the Java-based version works on a Windows system, so your choice on that platform is already made for you! Throughout this book, I use a Java-based Node Manager, as the examples are from a Windows environment. As for UNIX/Linux systems, you can use either version, with the script-based version being easier to configure from the security point of view. Other than this, the way the Node Manager interacts with server instances is essentially the same under the two versions.

Surprisingly, as critical as the Node Manager is for managing WebLogic Server, you really don’t access the process directly. You access the Node Manager through either the Admin Server or the WLST scripting tool—both act as Node Manager clients. When you use the Admin Server as the client, you do so through the Administration Console. When you are using the Node Manager from the command line, you do so by first invoking WLST and using it as the interface to run Node Manager commands. For the script-based Node Manager, you can use an SSH client to connect to the Node Manager remotely.

You can perform the following functions by connecting with the Node Manager process through WLST:

- You can control the Admin Server by starting, stopping, and restarting the server with the Node Manager.
- The Node Manager can stop and start as well as suspend any Managed Server. When you start or stop a Managed Server through the Administration Console, the Admin Server first accesses the Node Manager, which, in turn, performs the actual task.
- The Node Manager also monitors the Managed Servers and tries to restart a failed Managed Server.

This chapter provides a very simple introduction to the Node Manager and its capabilities. Chapter 2 shows you how to work with the Node Manager to perform various administrative tasks.

**Using the WebLogic Scripting Tool (WLST)**

Most application servers provide you with a good scripting tool. For example, IBM’s WebSphere has a scripting tool called `wsadmin` that is based on Jython, and JBoss has a similar scripting tool. Oracle WebLogic Server offers you a wonderful scripting tool called WebLogic Scripting Tool (WLST). WLST is a powerful tool, capable of performing several different types of administrative tasks for you, including configuration, management, and monitoring of tasks. As you’ll see in Chapter 2, you can connect to Node Manager through the WLST interface to manage the server instances. For ease of use, you can use simple Jython scripts as wrappers for WLST commands.

You can use WLST in interactive mode by invoking it at the command line. You can also use it in batch mode by putting WLST commands in scripts, and you can embed WLST commands in Java code by importing `weblogic.management.scripting.utils.WLSTInterpreter` into your Java class.

**Offline and Online WLST**

You can use WLST in online mode by connecting to an active Admin or Managed Server. When connected to the Admin Server, you can use WLST to configure a domain. As is the case with the Administration Console, WLST in online mode acts as a Java Management Extensions (JMX) client.
that manages the domain’s resources by modifying the server’s Configuration MBeans. Thus, WLST offers you all the domain management configuration capabilities as the Administration Console.

In offline mode, WLST helps you extend a domain, create domain templates, and create domains with those templates. Because you aren’t connected to an active Admin Server, you won’t be able to modify domain configuration in offline mode. In offline mode, WLST acts as an interface to the Node Manager, and you can issue WLST commands to start and stop Managed Server instances without connecting to the Admin Server. Note that you can’t start and stop Managed Servers through WLST without the Node Manager, however, as explained in Chapter 2.

CAUTION
Oracle recommends that you not use WLST in the offline mode to configure an active WebLogic domain. A running server ignores the offline commands, plus the Administration Console (and WLST online) can overwrite those commands.

Invoking WLST
In a Windows environment, you can invoke WLST through the Windows Start program and from the command line. The following sections show how to invoke WLST.

Starting WLST from the Start Program
You can invoke WLST in a Windows environment by simply selecting Start | Programs | Oracle | Oracle Home | WebLogic Server 12c | Tools | WebLogic Scripting Tool.

Invoking WLST from the Command Line
You can invoke WLST from the command line by using either the java weblogic.WLST command or the command script wlst.cmd. Before you can run the weblogic.WLST command, you must set the correct environment by issuing the setDomainEnv.cmd script, which is located in the WL_HOME\server\bin directory. In my case, this directory is C:\Oracle\Middleware\Oracle_Home\wlserver\server\bin, because the WL_HOME directory is defined as C:\Oracle\Middleware\Oracle_Home\wlserver on my Windows server. Once you set up the environment, you can invoke WLST with the Java command weblogic.WLST, located in the WL_HOME\common\bin directory:

    C:\Oracle\Middleware\Oracle_Home\wlserver\server\bin>setWLSEnv.cmd
    ...
    Your environment has been set.

    Once the environment has been set, you are ready to invoke WLST with the Java command weblogic.WLST:

    C:\Oracle\Middleware\Oracle_Home\wlserver\server\bin>java weblogic.WLST
    Initializing WebLogic Scripting Tool (WLST) ...
    Welcome to WebLogic Server Administration Scripting Shell
    Type help() for help on available commands
    wls://offline>

    Note that when you invoke WLST, by default, you’re in offline mode. You can only issue certain commands in offline mode, such as those that create a new domain or domain template,
for example. In offline mode, you can’t view performance data pertaining to any domain resource or add and remove users. To issue any online commands, you must first connect to the Admin Server using the connect command. Once you use WLST to connect to an Admin Server, you can manage the configuration of the domain and view performance data. Although you can connect to a Managed Server through WLST, you can’t modify the configuration for a Managed Server.

You can also invoke WLST by issuing the script wlst.cmd (wlst.sh in UNIX), as shown here:

```
C:\Oracle\Middleware\Oracle_Home\oracle_common\common\bin> wlst.cmd
CLASSPATH=C:\Oracle\MIDDLE-1\patch_wls1211\profiles\default\sys_manifest_classpath\weblogic_patch.jar;
C:\Oracle\MIDDLE-1\patch_ocp371\profiles\default\sys_manifest_classpath\weblogic_patch.jar;
C:\Oracle\MIDDLE-1\JROCKI-1.0-1\lib\tools.jar;
C:\Oracle\MIDDLE-1\WLSERV-1.1\server\lib\weblogic_sp.jar;
C:\Oracle\MIDDLE-1\WLSERV-1.1\server\lib\weblogic.jar;
C:\Oracle\MIDDLE-1\modules\features\weblogic.server.modules_12.1.1.0.jar;
C:\Oracle\MIDDLE-1\WLSERV-1.1\server\lib\webservices.jar;
C:\Oracle\MIDDLE-1\modules\ORGAPA-1.1\lib\ant-all.jar;
C:\Oracle\MIDDLE-1\modules\NETSFA-1.0_1\lib\ant-contrib.jar;
C:\Oracle\MIDDLE-1\util\config\10.3\config-launch.jar;
C:\Oracle\MIDDLE-1\WLSERV-1.1\common\derby\lib\derbynet.jar;
C:\Oracle\MIDDLE-1\WLSERV-1.1\common\derby\lib\derbyclient.jar;
C:\Oracle\MIDDLE-1\WLSERV-1.1\common\derby\lib\derbytools.jar;
Initializing WebLogic Scripting Tool (WLST)...
Welcome to WebLogic Server Administration Scripting Shell
Type help() for help on available commands
wls:/offline>
```

Note that you use the wlst.cmd script from the ORACLE_HOME\oracle_common\common\bin directory and not a directory specific to any particular WebLogic Server domain.

### Using WLST in Script Mode

Although you can use WLST in interactive mode to make configuration changes quickly in a development environment, WLST offers limited scripting language features and is cumbersome to use in a real-life WebLogic environment. You can use WLST scripts to automate server configuration and application deployment. A WLST script is a text file with the .py extension, and it includes WLST commands. WebLogic Server provides online and offline sample WLST scripts. For example, the Oracle-provided sample WLST script `clusterMedRecDomain.py` lets you create a WebLogic cluster with three Managed Servers. Similarly, the sample script named `basicWLSDomain.py` lets you create a simple WebLogic domain for development purposes, using the Oracle-supplied Basic WebLogic Server Domain template. You’ll find both of these scripts and a few others in the WL_HOME\common\templates\scripts\wlst directory (C:\Oracle\Middleware\Oracle_Home\wlserver\common\templates\scripts\wlst in my case).

You can invoke a WLST script (.py) by providing the name of the script as an argument to the java weblogic.WLST command, as shown here:

```
C:\Oracle\Middleware\wlserver_12.1\samples\domains\wl_server> java weblogic.WLST
C:\Oracle\Middleware\wlserver_12.1\samples\domains\medrec\shutdown.py
```
Here are the contents of the `shutdown.py` script:

```python
import os
if os.environ.has_key('wlsUserID'):
    wlsUserID = os.environ['wlsUserID']
if os.environ.has_key('wlsPassword'):
    wlsPassword = os.environ['wlsPassword']
connect(  url='t3://LOCALHOST:7001', adminServerName='examplesServer')
shutdown('examplesServerMedRecServer', 'Server', ignoreSessions='true')
exit()
```

Alternatively, you can first invoke WLST and specify the `execfile` command to execute the `shutdown.py` script.

```bash
wls:offline>
execfile('C:\MyOra\Middleware\Oracle_Home\wlserver\samples\domains\medrec\shutdown.py')
```

If you’re embedding WLST commands in a shell script or a Windows command script, invoke WLST with the `wlst.cmd` script (WL_HOME\common\bin\wlst.cmd). Doing this ensures that all the environment variables are set correctly. WebLogic Server also allows you to write all the WLST commands you enter during an interactive session to a file that you can later run as a WLST script. Simply issue the `startRecording` command to record all your interactive commands and issue the `stopRecording` command to stop the capturing of the commands, as shown here:

```bash
wls:/test_domain/serverConfig>
startRecording('C:\Oracle\Middleware\wls_12.1\test\test.py')
Started recording to C:\Oracle\Middleware\wls_12.1\test\test.py
```

Issue the WLST commands you want to capture in `test.py`. Once you’re done, stop the recording of the commands by issuing the `stopRecording` command:

```bash
wls:/test_domain/serverConfig> stopRecording()
Stopped recording to C:\Oracle\Middleware\wls_12.1\test\test.py
```

You can edit the `test.py` file and execute it as a WLST script.

### Connecting to a WebLogic Server Instance

In the offline mode, you aren’t connected to a running server. Use the `connect` command to connect to the Admin Server, as shown here:

```bash
wls:/offline> connect()
Please enter your username: weblogic
Please enter your password:
Please enter your server URL [t3://localhost:7001]:
Connecting to t3://localhost:7001 with userid weblogic...
Successfully connected to Admin Server 'examplesServer' that belongs to domain 'wl_server'.
Warning: An insecure protocol was used to connect to the server.
To ensure on-the-wire security, the SSL port or Admin port should be used instead.

```
wls:/wl_server/serverConfig>
```

In the example, you’ll notice a warning because I’m not using a secure port such as the administration port or an SSL port. Oracle recommends that you use either SSL or the administration port in a production system. You can ignore this warning in a development environment.

**TIP**

*To view the help topics, type* `help` *at the WLST command line. You must specify an argument for the help command; for example,* `help(connect)` *will give you information about using the connect command.*

You can also directly specify the administrator’s credentials at the command line, as shown here:

```
wls:/offline> connect('weblogic','welcome1','t3://localhost:7001')
Connecting to WebLogic Server instance running at t3://localhost:7001 as username weblogic...
Successfully connected to Admin Server 'ExamplesServer' that belongs to domain 'examples'.
wls:/mydomain/serverConfig>
```

As you can see, I had to supply the user credentials (the same ones used for the Administration Console) to connect to the Admin Server. Oracle recommends that you do this only when using WLST in interactive mode. The default behavior is for WLST to see if you have created a “user configuration file” to store the encrypted credentials and a “key file” with which the server can decrypt the credentials. If you start WLST from the domain directory from which you started the Admin Server, it can use the `boot.properties` file to get the encrypted credentials. (The `boot.properties` file is discussed in Chapter 2.)

When you use WLST in scripts, it’s safer not to use the clear text credentials in the script. You can use the `storeUserConfig` command to store the credentials in an encrypted form, following which you can specify the name of the user configuration file instead of the credentials. Here’s how to do this:

```
wls:/offline> connect(userConfigFile='C:\Oracle\test\myuserconfigfile.secure', userKeyFile='C:\Oracle\test\myuserkeyfile.secure')
Connecting to t3://localhost:7001 with userid username ...
Successfully connected to Admin Server 'AdminServer' that belongs to domain 'examples'.
wls:/examples/serverConfig>
```

In order to use the `userConfigFile` option, you must first issue the `storeUserConfig` command to create a user configuration file and its key file. The configuration file contains the encrypted credentials, and the key file contains the key the server uses for encrypting and decrypting the credentials. Here’s an example that shows how to do this:
Once you generate the user configuration file and the key file, you can supply the names of these two files instead of entering administrator credentials on the command line.

**Disconnecting from the Server**

You disconnect from a server by issuing the `disconnect` command, as shown here:

```
wls:/wl_server/serverConfig> disconnect()
Disconnected from WebLogic Server: examplesServer
wls:/offline>
```

To exit from WLST, use the `exit` command:

```
wls:/offline> exit()
Exiting WebLogic Scripting Tool.
```

By default, the server outputs all WLST messages or output to standard output, that is, to the screen. You can redirect all the messages to any file you wish by using the `redirect` command:

```
wls:/wl_server/serverConfig> redirect ('C:\Oracle\Middleware\wlserver_12.1\logs\wlst.log')
```

**Using the Help Command**

WLST has numerous commands that you can use in your daily work. You can check out these commands and their syntax using the `help` facility. Here’s a listing of all the `help` facility commands.

```
wls:/wl_server/serverConfig> help()
WLST is a command line scripting tool to configure and administer WebLogic Server. Try:

help('all')                  List all WLST commands available.
help('browse')               List commands for browsing the hierarchy.
help('common')               List the most commonly used commands.
help('control')              List commands for controlling the domain/server.
help('deployment')           List commands for deploying applications.
help('diagnostics')          List commands for performing diagnostics.
help('editing')              List commands for editing the configuration.
help('information')          List commands for displaying information.
help('lifecycle')            List commands for managing life cycle.
```

help('nodemanager')      List commands for using Node Manager.
help('offline')          List all offline commands available.
help('online')           List all online commands available.
help('storeadmin')       List all store admin commands.
help('trees')            List commands use to navigate MBean hierarchy.
help('variables')        List all global variables available.

Key WLST Command Groups
As I mentioned earlier, WLST offers a large number of commands to help perform various
management and programming tasks. Here’s a brief description of the key WLST command types.
Note that you can execute some commands only in offline mode and others in online mode.

Lifecycle Commands
You can use the lifecycle commands to manage the lifecycle of both the Admin and the Managed
Servers. WLST offers the start, startServer, suspend, resume, and migrate commands to control a
server lifecycle. Here are examples showing how to suspend and resume the Admin Server instance:

```
wls:/wl_server/serverConfig> suspend('examplesServer')
   ..Server examplesServer suspended successfully.
wls:/wl_server/serverConfig> resume('examplesServer')
   Server examplesServer resumed successfully.
wls:/wl_server/serverConfig>
```

Node Manager Commands
You can use the Node Manager commands to start, stop, and monitor server instances. Before you
can use Node Manager to manage server instances, you must connect WLST to the Node
Manager using the nmConnect command. The nmStart command lets you start a server instance
with the help of the Node Manager. Here’s how you use the nmConnect command to connect to
the Node Manager from WLST. First, make sure that the Node Manager is running; if not, you can
start it from the Windows Start command.

```
wls:/myserver/serverConfig> nmConnect('weblogic', 'welcome1', 'localhost',
   '7011', 'medrec',
   'C:\Oracle\Middleware\user_projects\domains\medrec','ssl')
   Connecting to Node Manager Server ...
   Successfully connected to Node Manager.
```

Chapter 2 explains other important Node Manager–related commands such as nmDisconnect,
nmEntroll, and nmkill.

Deployment Commands
Deployment commands such as deploy, undeploy, startApplication, and stopApplication enable
you to deploy, undeploy, and redeploy applications; update deployment plans; as well as start
and stop applications. Here’s how you execute the deploy command:

```
wls:/test_domain/serverConfig/Servers> deploy('myApp',
   'C:\Oracle\myApps\demos\app\myApp.ear',targets='ManagedServer1',
   planPath='C:\Oracle\myApps\demos\app\plan\plan.xml',timeout=120000)'
```
In this example, the *myApp* application is packaged in the form of a Java EAR file, *myApp.ear*. The server targets this application to the Managed Server named *ManagedServer1* using the deployment file in C:\Oracle\myApps\demos\app\plan\plan.xml. The server will wait for 120,000 milliseconds for the deployment to finish.

**Editing Commands**

You can use commands such as `get`, `set`, `edit`, `startEdit`, `stopEdit`, `save`, and `activate` to view and edit the MBean domain configuration hierarchy. You can edit and modify a domain's configuration in both offline and online modes. Oracle recommends that you change only the Admin Server's domain configuration MBeans, and not those of the Managed Servers, to avoid ending up with an inconsistent configuration. As you may recall, domain configuration changes are synchronized between the Admin Server and the Managed Server. You can, however, view the hierarchy for the Managed Server MBeans. Note that you must connect to the Admin Server before editing any of the configuration beans. Here's a simple example that shows how to use the `startEdit`, `stopEdit`, and `activate` commands:

```
  wls:/wl_server/edit> startEdit(30000, 60000)
  Starting an edit session ...
  Started edit session, please be sure to save and activate your changes once you are done.
  wls:/wl_server/edit !> stopEdit()
  Sure you would like to stop your edit session? (y/n)
  y
  Edit session has been stopped successfully.
  wls:/wl_server/edit !> activate(200000, block='true')
  Activating all your changes, this may take a while ... 
  the edit lock associated with this edit session is released once the activation is completed.
  Action completed.
  wls:/wl_server/edit>
```

**Diagnostic Commands**

Diagnostic commands such as `exportDiagnosticData` and `getAvailableCapturedImages` help you work with diagnostic data stored in the WebLogic Diagnostic Framework (WLDF) data stores. Chapter 6 shows how to use key WLST diagnostic commands.

**Summary**

This chapter introduced you to key WebLogic Server concepts and terminology. You learned how to install WebLogic Server, as well as how to upgrade it using the new Oracle Fusion Middleware Reconfiguration Wizard. The chapter also introduced you to the key WebLogic Server administrative tools such as the Administration Console, Node Manager, and WLST. WLST is an extremely powerful tool, capable of assisting with a wide variety of administrative tasks. I've attempted merely to introduce you to the WLST interface in this chapter. Chapter 2 shows you how to use WLST to manage a server's lifecycle. Similarly, other chapters show how you can effectively use the many powerful, yet easy-to-use WLST commands to perform other types of management tasks.

Now that you have a basic understanding of WebLogic Server, let's learn how to use WLST and Node Manager commands together to manage servers in the next chapter. Chapter 2 also explains the various server run states and how to manage them.
